TMS320C55x
Optimizing C/C++ Compiler
User’s Guide

Literature Number: SPRU281F
December 2003
IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

About This Manual

The Optimizing C/C++ Compiler User's Guide explains how to use these compiler tools:

- Compiler
- Optimizer
- Library-build utility
- C++ name demangler

The TMS320C55x™ C/C++ compiler accepts C and C++ code conforming to the International Organization for Standardization (ISO) standards for these languages, and produces assembly language source code for the TMS320C55x device. The compiler supports the 1989 version of the C language.

This user’s guide discusses the characteristics of the C/C++ compiler. It assumes that you already know how to write C/C++ programs. The C Programming Language (second edition), by Brian W. Kernighan and Dennis M. Ritchie, describes C based on the ISO C standard. You can use the Kernighan and Ritchie (hereafter referred to as K&R) book as a supplement to this manual. References to K&R C (as opposed to ISO C) in this manual refer to the C language as defined in first edition of Kernighan and Ritchie’s The C Programming Language.

Before you use the information about the C/C++ compiler in this user’s guide, you should install the C/C++ compiler tools.

Notational Conventions

This document uses the following conventions:

- The TMS320C55x device is referred to as C55x.
- Program listings, program examples, and interactive displays are shown in a special typeface. Examples use a bold version of the special typeface for emphasis; interactive displays use a bold version of the special typeface to distinguish commands that you enter from items that the system displays (such as prompts, command output, error messages, etc.).
Here is a sample of C code:

```c
#ifdef NDEBUG
#define assert(ignore) ((void)0)
#else
#define assert(expr) ((void)((_expr) ? 0 :
    (printf("Assertion failed, \"#_expr\", file `%s`, line %d\n, __FILE__, __LINE__), 
    abort (0) )))
#endif
```

- In syntax descriptions, the instruction, command, or directive is in a **bold** typeface and parameters are in *italics*. Portions of a syntax that are in bold face must be entered as shown; portions of a syntax that are in italics describe the type of information that should be entered. Syntax that is entered on a command line is centered in a bounded box:

  ```
  cl55 [options] [filenames] [−z [link_options] [object files]]
  ```

- Syntax used in a text file is left justified in a bounded box:

  ```
  inline return-type function-name ( parameter declarations ) { function }
  ```

- Square brackets ([ and ]) identify an optional parameter. If you use an optional parameter, you specify the information within the brackets; you don’t enter the brackets themselves. This is an example of a command that has an optional parameter:

  ```
  cl55 [options] [filenames] [−z [link_options] [object files]]
  ```

  The cl55 command has several optional parameters.

- Braces ({ and }) indicate that you must choose one of the parameters within the braces; you don’t enter the braces themselves. This is an example of a command with braces that are not included in the actual syntax but indicate that you must specify either the −c or −cr option:

  ```
  cl55 −z {−c | −cr} filenames [−o name.out] −l libraryname
  ```
Related Documentation From Texas Instruments

The following books describe the TMS320C55x and related support tools. To obtain a copy of any of these TI documents, call the Texas Instruments Literature Response Center at (800) 477-8924. When ordering, please identify the book by its title and literature number (located on the title page).

**TMS320C55x Assembly Language Tools User’s Guide** (literature number SPRU280) describes the assembly language tools (assembler, linker, and other tools used to develop assembly language code), assembler directives, macros, common object file format, and symbolic debugging directives for TMS320C55x devices.

**TMS320C55x DSP CPU Reference Guide** (literature number SPRU371) describes the architecture, registers, and operation of the CPU for the TMS320C55x DSPs.

**TMS320C55x DSP Peripherals Reference Guide** (literature number SPRU317) describes the peripherals, interfaces, and related hardware that are available on TMS320C55x DSPs.

**TMS320C55x DSP Algebraic Instruction Set Reference Guide** (literature number SPRU375) describes the TMS320C55x DSP algebraic instructions individually. Also includes a summary of the instruction set, a list of the instruction opcodes, and a cross-reference to the mnemonic instruction set.

**TMS320C55x DSP Mnemonic Instruction Set Reference Guide** (literature number SPRU374) describes the TMS320C55x DSP mnemonic instructions individually. Also includes a summary of the instruction set, a list of the instruction opcodes, and a cross-reference to the algebraic instruction set.

**TMS320C55x DSP Programmer’s Guide** (literature number SPRU376) describes ways to optimize C and assembly code for the TMS320C55x DSPs and explains how to write code that uses special features and instructions of the DSPs.

**TMS320C55x Technical Overview** (literature number SPRU393). This overview is an introduction to the TMS320C55x DSPs, the latest generation of fixed-point DSPs in the TMS320C5000™ DSP platform. Like the previous generations, this processor is optimized for high performance and low-power operation. This book describes the CPU architecture, low-power enhancements, and embedded emulation features.

**Code Composer User’s Guide** (literature number SPRU328) explains how to use the Code Composer development environment to build and debug embedded real-time DSP applications.

1 Introduction ................................................................. 1-1
Provides an overview of the TMS320C55x software development tools, specifically the compiler.

1.1 Software Development Tools Overview .......................... 1-2
1.2 C/C++ Compiler Overview .......................................... 1-5
  1.2.1 ISO Standard .................................................. 1-5
  1.2.2 Output Files .................................................. 1-6
  1.2.3 Compiler Interface ............................................ 1-6
  1.2.4 Compiler Operation .......................................... 1-7
  1.2.5 Utilities ....................................................... 1-7
1.3 The Compiler and Code Composer Studio ....................... 1-8

2 Using the C/C++ Compiler ........................................... 2-1
Describes how to operate the compiler. Contains instructions for invoking the compiler, which compiles, assembles, and links a source file. Discusses the compiler options, compiler errors, and interlisting.

2.1 About the Compiler .................................................. 2-2
2.2 Invoking the C/C++ Compiler ..................................... 2-4
2.3 Changing the Compiler's Behavior With Options ............ 2-5
  2.3.1 Frequently Used Options ................................... 2-17
  2.3.2 Selecting the Device Version (−v Option) ............. 2-21
  2.3.3 Symbolic Debugging and Profiling Options .......... 2-23
  2.3.4 Specifying Filenames ....................................... 2-24
  2.3.5 Changing How the Compiler Intercepts Filenames (−fa, −fc, −fg, −fo, and −fp Options) ............... 2-24
  2.3.6 Changing How the Compiler Intercepts and Names Extensions (−ea, −ec, −eo, −ep, and −es Options) ............. 2-25
  2.3.7 Specifying Directories ..................................... 2-26
  2.3.8 Options That Control the Assembler ................. 2-27
  2.3.9 Deprecated Options ....................................... 2-30
2.4 Using Environment Variables ...................................... 2-31
  2.4.1 Specifying Directories (C_DIR and C55X_C_DIR) .... 2-31
  2.4.2 Setting Default Compiler Options (C_OPTION and C55X_C_OPTION) ........................................ 2-31

## Contents

### 3.9 What Kind of Optimization Is Being Performed? .......................... 3-16
- 3.9.1 Cost-Based Register Allocation ...................................... 3-17
- 3.9.2 Alias Disambiguation .................................................. 3-17
- 3.9.3 Branch Optimizations and Control-Flow Simplification .......... 3-17
- 3.9.4 Data Flow Optimizations .............................................. 3-19
- 3.9.5 Expression Simplification ............................................. 3-19
- 3.9.6 Inline Expansion of Functions .................................... 3-21
- 3.9.7 Induction Variables and Strength Reduction .................... 3-22
- 3.9.8 Loop-Invariant Code Motion ...................................... 3-22
- 3.9.9 Loop Rotation ......................................................... 3-22
- 3.9.10 Autoincrement Addressing ....................................... 3-23
- 3.9.11 Repeat Blocks ....................................................... 3-23
- 3.9.12 Tail Merging .......................................................... 3-24

### 4 Linking C/C++ Code ............................................................. 4-1

Describes how to link in a separate step or as part of the compile step, and how to meet the special requirements of linking C/C++ code.

- 4.1 Invoking the Linker (−z Option) ........................................ 4-2
  - 4.1.1 Invoking the Linker As a Separate Step .......................... 4-2
  - 4.1.2 Invoking the Linker As Part of the Compile Step ............... 4-3
  - 4.1.3 Disabling the Linker (−c Option) .................................. 4-4
- 4.2 Linker Options ............................................................... 4-5
- 4.3 Controlling the Linking Process ....................................... 4-8
  - 4.3.1 Linking With Run-Time-Support Libraries ....................... 4-8
  - 4.3.2 Run-Time Initialization ............................................. 4-9
  - 4.3.3 Initialization By the Interrupt Vector ............................ 4-9
  - 4.3.4 Global Object Constructors ...................................... 4-10
  - 4.3.5 Specifying the Type of Initialization ............................ 4-10
  - 4.3.6 Specifying Where to Allocate Sections in Memory ............ 4-11
  - 4.3.7 A Sample Linker Command File ................................ 4-12

### 5 TMS320C55x C/C++ Language ................................................. 5-1

Discusses the specific characteristics of the compiler as they relate to the ISO C specification.

- 5.1 Characteristics of TMS320C55x C ...................................... 5-2
  - 5.1.1 Identifiers and Constants ......................................... 5-2
  - 5.1.2 Data Types ........................................................... 5-2
  - 5.1.3 Conversions .......................................................... 5-3
  - 5.1.4 Expressions .......................................................... 5-3
  - 5.1.5 Declaration ........................................................... 5-3
  - 5.1.6 Preprocessor .......................................................... 5-4
- 5.2 Characteristics of TMS320C55x C++ .................................... 5-5
- 5.3 Data Types ................................................................. 5-6
### 5.4 Keywords
- **5.4.1 The const Keyword** 5-8
- **5.4.2 The ioprt Keyword** 5-9
- **5.4.3 The interrupt Keyword** 5-12
- **5.4.4 The onchip Keyword** 5-12
- **5.4.5 The restrict Keyword** 5-13
- **5.4.6 The volatile Keyword** 5-14

### 5.5 Register Variables and Parameters 5-15

### 5.6 The asm Statement 5-16

### 5.7 Pragma Directives 5-17
- **5.7.1 The CODE_SECTION Pragma** 5-18
- **5.7.2 The C54X_CALL and C54X_FAR_CALL Pragmas** 5-19
- **5.7.3 The DATA_ALIGN Pragma** 5-21
- **5.7.4 The DATA_SECTION Pragma** 5-22
- **5.7.5 The FAR Pragma** 5-23
- **5.7.6 The FUNC_CANNOT_INLINE Pragma** 5-24
- **5.7.7 The FUNC_EXT_CALLED Pragma** 5-24
- **5.7.8 The FUNC_IS_PURE Pragma** 5-25
- **5.7.9 The FUNC_IS_SYSTEM Pragma** 5-26
- **5.7.10 The FUNC_NEVER_RETURNS Pragma** 5-26
- **5.7.11 The FUNC_NO_GLOBAL_ASG Pragma** 5-27
- **5.7.12 The FUNC_NO_IND_ASG Pragma** 5-27
- **5.7.13 The INTERRUPT Pragma** 5-28
- **5.7.14 The MUST_ITERATE Pragma** 5-28
- **5.7.15 The UNROLL Pragma** 5-30

### 5.8 Generating Linknames 5-32

### 5.9 Initializing Static and Global Variables 5-33
- **5.9.1 Initializing Static and Global Variables With the Linker** 5-33
- **5.9.2 Initializing Static and Global Variables With the Const Type Qualifier** 5-34

### 5.10 Changing the ISO C Language Mode (−pk, −pr, and −ps Options) 5-35
- **5.10.1 Compatibility With K&R C (−pk Option)** 5-35
- **5.10.2 Enabling Strict ISO Mode and Relaxed ISO Mode (−ps and −pr Options)** 5-37
- **5.10.3 Enabling Embedded C++ Mode (−pe Option)** 5-37

### 5.11 Compiler Limits 5-38
6 Run-Time Environment ......................................................... 6-1

Contains technical information on how the compiler uses the C55x architecture. Discusses memory, register, and function calling conventions, and system initialization. Provides the information needed for interfacing assembly language to C/C++ programs.

6.1 Memory .............................................................................. 6-2
   6.1.1 Small Memory Model ..................................................... 6-2
   6.1.2 Large Memory Model .................................................... 6-3
   6.1.3 Huge Memory Model ..................................................... 6-3
   6.1.4 Sections ........................................................................ 6-4
   6.1.5 C/C++ System Stack ..................................................... 6-6
   6.1.6 Dynamic Memory Allocation ........................................ 6-7
   6.1.7 Initialization of Variables ............................................. 6-7
   6.1.8 Allocating Memory for Static and Global Variables ........... 6-9
   6.1.9 Field/Structure Alignment ............................................. 6-9

6.2 Character String Constants .................................................. 6-11

6.3 Register Conventions ......................................................... 6-12
   6.3.1 Status Registers .......................................................... 6-14

6.4 Function Structure and Calling Conventions ............................ 6-16
   6.4.1 How a Function Makes a Call ......................................... 6-17
   6.4.2 How a Called Function Responds .................................... 6-20
   6.4.3 Accessing Arguments and Locals .................................... 6-21

6.5 Interfacing C/C++ With Assembly Language ............................ 6-22
   6.5.1 Using Assembly Language Modules with C/C++ Code ...... 6-22
   6.5.2 Accessing Assembly Language Variables From C/C++ ...... 6-24
   6.5.3 Using Inline Assembly Language .................................... 6-27
   6.5.4 Using Intrinsics to Access Assembly Language Statements ... 6-28

6.6 Interrupt Handling ............................................................. 6-38
   6.6.1 General Points About Interrupts ..................................... 6-38
   6.6.2 Saving Context on Interrupt Entry ................................... 6-38
   6.6.3 Using C/C++ Interrupt Routines ..................................... 6-39
   6.6.4 Intrinsics for Interrupts .................................................. 6-39

6.7 Extended Addressing of Data in P2 Reserved Mode .................. 6-40
   6.7.1 Placing Data in Extended Memory ................................... 6-41
   6.7.2 Obtaining the Full Address of a Data Object in Extended Memory ... 6-41
   6.7.3 Accessing Far Data Objects ........................................... 6-42

6.8 The .const Sections in Extended Memory ............................... 6-43

6.9 System Initialization .......................................................... 6-45
   6.9.1 Automatic Initialization of Variables ............................... 6-45
   6.9.2 Global Object Constructors .......................................... 6-46
   6.9.3 Initialization Tables ..................................................... 6-46
   6.9.4 Autointialization of Variables at Run Time ....................... 6-49
   6.9.5 Initialization of Variables at Load Time ........................... 6-50
7 Run-Time-Support Functions

Describes the libraries and header files included with the C/C++ compiler, as well as the macros, functions, and types that they declare. Summarizes the run-time-support functions according to category (header) and provides an alphabetical summary of the run-time-support functions.

7.1 Libraries

7.1.1 Modifying a Library Function

7.1.2 Building a Library With Different Options

7.2 The C I/O Functions

7.2.1 Overview of Low-Level I/O Implementation

7.2.2 Adding a Device For C I/O

7.3 Header Files

7.3.1 Diagnostic Messages (assert.h/cassert)

7.3.2 Character-Typing and Conversion (ctype.h/cctype)

7.3.3 Error Reporting (errno.h/cerrno)

7.3.4 Extended Addressing Functions (extaddr.h)

7.3.5 Low-Level Input/Output Functions (file.h)

7.3.6 Limits (float.h/cfloat and limits.h/climits)

7.3.7 Format Conversion of Integer Types (inttypes.h)

7.3.8 Alternative Spellings (iso646.h/ciso646)

7.3.9 Floating-Point Math (math.h/cmath)

7.3.10 Nonlocal Jumps (setjmp.h/csetjmp)

7.3.11 Variable Arguments (stdarg.h/cstdarg)

7.3.12 Standard Definitions (stddef.h/cstddef)

7.3.13 Integer Types (stdint.h)

7.3.14 Input/Output Functions (stdio.h/cstdio)

7.3.15 General Utilities (stdlib.h/cstdlib)

7.3.16 String Functions (string.h/cstring)

7.3.17 Time Functions (time.h/ctime)

7.3.18 Exception Handling (exception and stdexcept)

7.3.19 Dynamic Memory Management (new)

7.3.20 Run-Time Type Information (typeinfo)

7.4 Summary of Run-Time-Support Functions and Macros

7.5 Description of Run-Time-Support Functions and Macros
8 Library-Build Utility ............................................................... 8-1
Describes the utility that custom-makes run-time-support libraries for the options used to compile code. You can use this utility to install header files in a directory and to create custom libraries from source archives.
8.1 Invoking the Library-Build Utility ........................................... 8-2
8.2 Library-Build Utility Options ................................................. 8-3
8.3 Options Summary ................................................................. 8-4

9 C++ Name Demangler .............................................................. 9-1
Describes the C++ name demangler and tells you how to invoke and use it.
9.1 Invoking the C++ Name Demangler ......................................... 9-2
9.2 C++ Name Demangler Options ............................................. 9-2
9.3 Sample Usage of the C++ Name Demangler .............................. 9-3

10 Glossary .................................................................................. A-1
# Figures

The TMS320C55x™ is supported by a set of software development tools, which includes an optimizing C/C++ compiler, an assembler, a linker, and assorted utilities.

This chapter provides an overview of these tools and introduces the features of the optimizing C/C++ compiler. The assembler and linker are discussed in detail in the TMS320C55x Assembly Language Tools User’s Guide.

1.1 Software Development Tools Overview

Figure 1-1 illustrates the C55x software development flow. The shaded portion of the figure highlights the most common path of software development for C/C++ language programs. The other portions are peripheral functions that enhance the development process.

Figure 1-1. TMS320C55x Software Development Flow
The following list describes the tools that are shown in Figure 1–1:

- **The C/C++ compiler** accepts C/C++ source code and produces C55x assembly language source code. An optimizer is part of the compiler. The optimizer modifies code to improve the efficiency of C/C++ programs. See Chapter 2, *Using the C/C++ Compiler*, for information about how to invoke the C compiler and the optimizer.

- **The assembler** translates assembly language source files into machine language object files. The TMS320C55x tools include two assemblers. The mnemonic assembler accepts C54x and C55x mnemonic assembly source files. The algebraic assembler accepts C55x algebraic assembly source files. The machine language is based on common object file format (COFF). The TMS320C55x *Assembly Language Tools User’s Guide* explains how to use the assembler.

- **The linker** combines object files into a single executable object module. As it creates the executable module, it performs relocation and resolves external references. The linker accepts relocatable COFF object files and object libraries as input. See Chapter 4, *Linking C/C++ Code*, for information about invoking the linker. See the TMS320C55x *Assembly Language Tools User’s Guide* for a complete description of the linker.

- **The archiver** allows you to collect a group of files into a single archive file, called a library. Additionally, the archiver allows you to modify a library by deleting, replacing, extracting, or adding members. One of the most useful applications of the archiver is building a library of object modules. The TMS320C55x *Assembly Language Tools User’s Guide* explains how to use the archiver.

- You can use the library-build utility to build your own customized run-time-support library (see Chapter 8, *Library-Build Utility*). Standard run-time-support library functions are provided as source code in rts.src. The run-time-support libraries contain the ANSI/ISO standard run-time-support functions, compiler-utility functions, floating-point arithmetic functions, and C I/O functions that are supported by the C55x compiler. See Chapter 7, *Run-Time-Support Functions*, for more information.

- **The C55x debugger** accepts executable COFF files as input, but most EPROM programmers do not. The hex conversion utility converts a COFF object file into TI-Tagged, ASCII-hex, Intel, Motorola-S, or Tektronix object format. The converted file can be downloaded to an EPROM programmer. The TMS320C55x *Assembly Language Tools User’s Guide* explains how to use the hex conversion utility.
The absolute lister accepts linked object files as input and creates .abs files as output. You can assemble these .abs files to produce a listing that contains absolute, rather than relative, addresses. Without the absolute lister, producing such a listing would be tedious and would require many manual operations. The TMS320C55x Assembly Language Tools User’s Guide explains how to use the absolute lister.

The cross-reference lister uses object files to produce a cross-reference listing showing symbols, their definitions, and their references in the linked source files. The TMS320C55x Assembly Language Tools User’s Guide explains how to use the cross-reference lister.

The C++ name demangler is a debugging aid that translates each mangled name it detects to its original name found in the C++ source code. For more information, see Chapter 9, C++ Name Demangler.

The main product of this development process is a module that can be executed in a TMS320C55x device. You can use one of several debugging tools to refine and correct your code. Available products include:

- An instruction-accurate software simulator
- An extended development system (XDS510™) emulator

These tools are accessed within Code Composer Studio. For more information, see the Code Composer Studio User’s Guide.
1.2 C/C++ Compiler Overview

The C55x C/C++ compiler is a full-featured optimizing compiler that translates standard ANSI/ISO C/C++ programs into C55x assembly language source. The following sections describe the key features of the compiler.

1.2.1 ISO Standard

The following features pertain to ISO standards:

- **ISO-standard C**

  The C55x C/C++ compiler fully conforms to the ISO C standard as defined by the ISO specification and described in the second edition of Kernighan and Ritchie’s *The C Programming Language* (K&R). The ISO C standard supercedes and is the same as the ANSI C standard.

- **ISO-standard C++**

  The C55x C/C++ compiler supports C++ as defined by the ISO C++ Standard and described in Ellis and Stroustrup’s *The Annotated C++ Reference Manual* (ARM). The compiler also supports embedded C++.

  For a description of unsupported C++ features, see section 5.2, *Characteristics of TMS320C55x C++*, on page 5-5.

- **ISO-standard run-time support**

  The compiler tools come with a complete run-time library. All library functions conform to the ISO C library standard. The library includes functions for standard input and output, string manipulation, dynamic memory allocation, data conversion, time-keeping, trigonometry, and exponential and hyperbolic functions. Functions for signal handling are not included, because these are target-system specific.

  The C++ library includes the ISO C subset as well as those components necessary for language support.

  For more information, see Chapter 7, *Run-Time-Support Functions*.  

1.2.2 Output Files

The following features pertain to output files created by the compiler:

- **Assembly source output**
  The compiler generates assembly language source files that you can inspect easily, enabling you to see the code generated from the C/C++ source files.

- **COFF object files**
  Common object file format (COFF) allows you to define your system’s memory map at link time. This maximizes performance by enabling you to link C/C++ code and data objects into specific memory areas. COFF also supports source-level debugging.

- **EPROM programmer data files**
  For stand-alone embedded applications, the compiler has the ability to place all code and initialization data into ROM, allowing C/C++ code to run from reset. The COFF files output by the compiler can be converted to EPROM programmer data files by using the hex conversion utility. For more information about the hex conversion utility, see the TMS320C55x Assembly Language Tools User’s Guide.

1.2.3 Compiler Interface

The following features pertain to interfacing with the compiler:

- **Compiler program**
  The compiler tools allow you to compile, assemble, and link programs in a single step. For more information, see section 2.2, *Invoking the C/C++ Compiler*, on page 2-4.

- **Flexible assembly language interface**
  The compiler has straightforward calling conventions, so you can write assembly and C functions that call each other. For more information, see Chapter 6, *Run-Time Environment.*
1.2.4 Compiler Operation

The following features pertain to the operation of the compiler:

- **Integrated preprocessor**
  The C/C++ preprocessor is integrated with the parser, allowing for faster compilation. Standalone preprocessing or preprocessed listing is also available. For more information, see section 2.5, *Controlling the Preprocessor*, on page 2-33.

- **Optimization**
  The compiler uses a sophisticated optimization pass that employs several advanced techniques for generating efficient, compact code from C/C++ source. General optimizations can be applied to any C/C++ code, and C55x specific optimizations take advantage of the features specific to the C55x architecture. For more information about the C/C++ compiler’s optimization techniques, see Chapter 3, *Optimizing Your Code*.

1.2.5 Utilities

The following features pertain to the compiler utilities:

- The **library-build utility** is a significant feature of the compiler utilities. The library-build utility lets you custom-build object libraries from source for any combination of run-time models or target CPUs. For more information, see Chapter 8, *Library-Build Utility*.

- The **C++ name demangler** is a debugging aid that translates each mangled name it detects to its original name found in the C++ source code. For more information, see Chapter 9, *C++ Name Demangler*.
1.3 The Compiler and Code Composer Studio

Code Composer Studio provides a graphical interface for using the code generation tools.

A Code Composer Studio project keeps track of all information needed to build a target program or library. A project records:

- Filenames of source code and object libraries
- Compiler, assembler, and linker options
- Include file dependencies

When you build a project with Code Composer Studio, the appropriate code generation tools are invoked to compile, assemble, and/or link your program.

Compiler, assembler, and linker options can be specified within Code Composer Studio’s Build Options dialog. Nearly all command line options are represented within this dialog. Options that are not represented can be specified by typing the option directly into the editable text box that appears at the top of the dialog.

The information in this book describes how to use the code generation tools from the command line interface. For information on using Code Composer Studio, see the Code Composer Studio User’s Guide. For information on setting code generation tool options within Code Composer Studio, see the Code Generation Tools online help.
The compiler translates your source program into code that the TMS320C55x™ can execute. The source code must be compiled, assembled, and linked to create an executable object file. All of these steps are performed at once by using the compiler, cl55. This chapter provides a complete description of how to use cl55 to compile, assemble, and link your programs.

This chapter also describes the preprocessor, optimizer, inline function expansion features, and interlisting.

2.1 About the Compiler

The compiler cl55 lets you compile, assemble, and optionally link in one step. The compiler performs the following steps on one or more source modules:

- The **code generator**, which includes the parser and optimizer, accepts C/C++ source code and produces C55x assembly language source code.
  
  You can compile C and C++ files in a single command—the compiler uses filename extensions to distinguish between them (see section 2.3.4, *Specifying Filenames*, for more information).

- The **assembler** generates a COFF object file.

- The **linker** combines your object files to create an executable object file. The link step is optional, so you can compile and assemble many modules independently and link them later. See Chapter 4, *Linking C/C++ Code*, for information about linking files.

By default, the compiler does not perform the link step. You can invoke the linker by using the −z compiler option. Figure 2−1 illustrates the path the compiler takes with and without using the linker.
Figure 2-1. The C/C++ Compiler Overview

For a complete description of the assembler and the linker, see the TMS320C55x Assembly Language Tools User's Guide.
2.2 Invoking the C/C++ Compiler

To invoke the compiler, enter:

```
c55 [options] [filenames] [-z [link_options] [object files]]
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>cl55</code></td>
<td>Command that runs the compiler and the assembler</td>
</tr>
<tr>
<td><code>options</code></td>
<td>Options that affect the way the compiler processes input files (the options are listed in Table 2-1 on page 2-6)</td>
</tr>
<tr>
<td><code>filenames</code></td>
<td>One or more C/C++ source files, assembly source files, or object files</td>
</tr>
<tr>
<td><code>−z</code></td>
<td>Option that invokes the linker. See Chapter 4, Linking C/C++ Code, for more information about invoking the linker.</td>
</tr>
<tr>
<td><code>link_options</code></td>
<td>Options that control the linking process</td>
</tr>
<tr>
<td><code>object files</code></td>
<td>Name of the additional object files for the linking process</td>
</tr>
</tbody>
</table>

The arguments to `cl55` are of three types: compiler options, linker options, and files. The `−z` linker option is the signal that linking is to be performed. If the `−z` linker option is used, compiler options must precede the `−z` linker options, and other linker options must follow the `−z` linker option. Source code filenames must be placed before the `−z` linker option. Additional object file filenames may be placed after the `−z` linker option.

As an example, if you want to compile two files named `symtab.c` and `file.c`, assemble a third file named `seek.asm`, and link to create an executable file, you enter:

```
c55 symtab.c file.c seek.asm -z -llnk.cmd -lrts55.lib
```

Entering this command produces the following output:

```
[symtab.c]
[file.c]
[seek.asm]
<Linking>
```
2.3 Changing the Compiler’s Behavior With Options

Options control the operation of the compiler. This section provides a description of option conventions and an option summary table. It also provides detailed descriptions of the most frequently used options, including options used for type-checking and assembling. For the most current summary of the options, enter cl55 with no parameters on the command line.

The following apply to the compiler options:

- Options are preceded by one or two hyphens.
- Options are case sensitive.
- Options are either single letters or sequences of characters.
- Individual options cannot be combined.
- An option with a required parameter should be specified with an equal sign before the parameter to clearly associate the parameter with the option. For example, the option to undefine a name can be expressed as −U=name. Although not recommended, you can separate the option and the parameter with or without a space, as in −U name or −U name.
- An option with an optional parameter should be specified with an equal sign before the parameter to clearly associate the parameter with the option. For example, the option to specify the maximum amount of optimization can be expressed as −O=3. Although not recommended, you can specify the parameter directly after the option, as in −O3. No space is allowed between the option and the optional parameter, so −O 3 is not accepted.
- Files and options except the −z option can occur in any order. The −z option must follow all other compiler options and precede any linker options.

You can define default options for the shell by using the C_OPTION or C55X_C_OPTION environment variable. For more information on the C_OPTION environment variable, see section 2.4.2, Setting Default Compiler Options (C_OPTION and C55X_C_OPTION), on page 2-31.

Table 2–1 summarizes all options (including linker options) and shows their syntax. Use the page references in the table for more complete descriptions of the options.
### Table 2-1. Compiler Options Summary

<td>−−xml_info_file=file</td>
<td>Produces a detailed link information file</td>
<td>4-7</td>
</tr>
</tbody>
</table>
2.3.1 Frequently Used Options

Following are detailed descriptions of options that you will probably use frequently:

-\@=filename
  Appends the contents of a file to the command line. You can use this option to avoid limitations on command line length imposed by the host operating system. Use a # or ; at the beginning of a line in the command file to embed comments.

Within the command file, filenames or option parameters containing embedded spaces or hyphens must be surrounded by quotation marks. For example: “this-file.obj”

-abs
  Produces an absolute listing file when used after the \-z option. Note that you must use the \-o option (after \-z) to specify the .out file for the absolute lister, even if you use a linker command file that already uses \-o.

-b
  Generates an auxiliary information file that you can refer to for information about stack size and function calls. The filename is the C/C++ source filename with an .aux extension.

-C
  Suppresses the linker and overrides the \-z option, which specifies linking. Use this option when you have \-z specified in the C_OPTION or C55X_C_OPTION environment variable and you do not want to link. For more information, see section 4.1.3, Disabling the Linker, (\-c Option), on page 4-4.

-call=value
  Forces compiler compatibility with specific calling conventions. Early versions of the C55x compiler used a calling convention that was less efficient. The new calling conventions address these inefficiencies. The \-call option supports compatibility with existing code which either calls or is called by assembly code using the original convention. Using \-call=c55_compat forces the compiler to generate code that is compatible with the original calling convention. Using \-call=c55_new forces the compiler to use the new calling convention.

The compiler uses the new convention by default, except when compiling for P2 reserved mode, which sets the default to the original convention. Within a single executable, only one calling convention can be used. The linker enforces this rule.
### Changing the Compiler’s Behavior With Options

**--consultant** Generates compile time loop information through the Compiler Consultant Advice tool. See the *TMS320C55x Code Composer Studio Online Help* for more information about the Compiler Consultant Advice tool.

**-D=name[=def]** Predefines the constant `name` for the preprocessor. This is equivalent to inserting `#define name def` at the top of each C/C++ source file. If the optional `[=def]` is omitted, the `name` is set to 1.

**-I=directory** Adds `directory` to the list of directories that the compiler searches for `#include` files. You can use this option several times to define several directories; be sure to separate `-I` options with spaces. If you do not specify a directory name, the preprocessor ignores the `-I` option. For more information, see section 2.5.2.1, *Changing the #include File Search Path With the –I Option*, on page 2-35.

**-k** Keeps the assembly language output of the compiler. Normally, the compiler deletes the output assembly language file after assembly is complete.

**-mb** Specifies that all data memory resides on-chip. This option allows the compiler to optimize using C55x dual MAC instructions. You must ensure that your linker command file places all such data into on-chip memory.

**-mc** Allows constants that are normally placed in a `.const` section to be treated as read-only, initialized static variables. This is useful when using the small memory model or on P2 reserved mode hardware. It allows the constant values to be loaded into extended memory while the space used to hold the values at run time is still in the single data page used by the program.

**-mg** By default, the compiler and assembler use mnemonic assembly: the compiler generates mnemonic assembly output, and the assembler will only accept mnemonic assembly input files. When this option is specified, the compiler and assembler use algebraic assembly. You must use this option to assemble algebraic assembly input files, or to compile C code containing algebraic asm statements. Algebraic and mnemonic source code cannot be mixed in a single source file.
Changing the Compiler’s Behavior With Options

−mo
Places the code for each function in a file in a separate subsection. Unless the function is an interrupt, the subsection is marked for conditional linking with the .clink directive.

Using the −mo option can result in overall code size growth if all or nearly all the functions are referenced and the functions have many references to each other. This is because a function calling another function in the same file can no longer be guaranteed that the called function is within range of a short call instruction and thus is required to use a longer call instruction.

−mr
Prevents the compiler from generating the hardware blockrepeat, localrepeat, and repeat instructions. This option is only useful when −O2 or −O3 is specified.

−ms
Optimizes for code space instead of for speed.

−n
Compiles only. The specified source files are compiled, but not assembled or linked. This option overrides −z. The output is assembly language output from the compiler.

--nomacx
Prevents the expansion of macros when source is output.

--ptrdiff_t_16
Changes the prtdiff_t type to an int (16 bits). The prtdiff_t type, defined in the stddef.h or cstddef header, is a signed integer type that is the data type resulting from the subtraction of two pointers. This option ensures the prtdiff_t type is an int.

−q
Suppresses the compilation output messages when you invoke cl55 and run the tools. The compilation output messages are the C/C++ messages in square brackets ([ ]).

−qq
Suppresses all output messages when you invoke cl55 and run the tools.
Changing the Compiler’s Behavior With Options

−s
Invokes the interlist feature, which interweaves optimizer comments or C/C++ source with assembly source. If the optimizer is invoked (−O option), optimizer comments are interlisted with the assembly language output of the compiler, which may rearrange code substantially. If the optimizer is not invoked, C/C++ source statements are interlisted with the assembly language output of the compiler, allowing you to inspect the code generated for each C/C++ statement. The −s option implies the −k option. For more information about using the interlist feature with the optimizer, see section 3.7, Using Interlist With Optimization, on page 3-12.

−ss
Invokes the interlist feature, which interweaves original C/C++ source with compiler-generated assembly language. If the optimizer is invoked (−O option) along with this option, your code might be reorganized substantially. For more information, see section 2.10, Using Interlist, on page 2-49.

−U=name
Undefines the predefined constant name. This option overrides any −D options for the specified constant.

−v=device
Determines the processor for which instructions are generated. For information on legal values, see section 2.3.2, Selecting the Device Version (−v Option), on page 2-21.

−−verbose
Displays the banner while compiling. This includes the compiler version number and copyright information.

−version
Displays the tool version numbers.

−z
Runs the linker on the specified object files. This option and its parameters follow all other options on the command line. All arguments that follow −z are passed to the linker. For more information, see section 4.1, Invoking the Linker, on page 4-2.
2.3.2 Selecting the Device Version (−v Option)

The −v option is used to indicate which target device or devices will be used to execute the code being generated. Using the −vdevice:[revision] option specifies the target for which instructions should be generated. The device parameter is usually the last four digits of the TMS320C55x part number. For example, to specify the TMS320VC5510 DSP device, you would use −v5510. The −vdevice option without a rev number generates code that will run on all current silicon revisions for that device. However, if you specify a revision number (e.g., −v5510:1), the compiler may be able to generate more optimal code for that revision. You can use multiple −v options to specify multiple devices and revision numbers. Certain combinations may not be permitted.

Non-Use vs. Use of −v

If the −v option is not used, the compiler generates code that will run on all known TMS320C55x devices. However, code which will execute on all devices is not optimal for any device. Through careful use of −v, you avoid workarounds for, and detection of, hardware defects in devices that you are not using.

The −vdevice:0 option generates code according to the device’s original hardware specification.

Note that the revision specifier can be more than one digit, if necessary. A revision numbered as 1.1 would be specified as −vdevice:1.1.

This information allows the tools to enable features available to specific devices or revisions if all specified targets have the feature. Similarly, any hardware defect workarounds or detections will only be done if they apply to the designated target(s).

You can safely generate code for your device without specifying the exact revision. For instance, you can use −v5509 to generate optimized code compatible with all versions of the C5509. If you want to further optimize to the exact revision in your product, you must know and specify that particular revision number using the −v option.

If your software is to run on a product or line of products that use different device revisions or even different devices for different models of the product, you can specify multiple device revisions (for example, −v5510:2.1 −v5510:2.2 −v5509) to produce code suitable for the designated hardware.

Generally, using −v to restrict code generation to a particular set of devices results in better performing code.
The devices and revisions currently supported are:

<table>
<thead>
<tr>
<th>DEVICE</th>
<th>REV</th>
</tr>
</thead>
<tbody>
<tr>
<td>core</td>
<td>0, 1, 1.0, 1.1, 1.x, 2, 2.0, 2.1, 2.2, 3, 3.0</td>
</tr>
<tr>
<td>5510</td>
<td>0, 0.0, 1, 1.0, 1.0A, 1.1, 1.1A, 1.2, 1.x, 2, 2.0, 2.1, 2.2, 2.x, 3, 3.0</td>
</tr>
<tr>
<td>5501</td>
<td>-, 1, 1.0</td>
</tr>
<tr>
<td>5502</td>
<td>-, 1, 1.0</td>
</tr>
<tr>
<td>5509</td>
<td>A, B, C, D, E</td>
</tr>
<tr>
<td>5561</td>
<td>-, 1, 1.0, 2, 2.0, 2.1, 2.x</td>
</tr>
<tr>
<td>DA250</td>
<td>1, 1.0, 1.1, 1.x, 2, 2.0, 2.05, 2.1, 2.x, 3, 3.0</td>
</tr>
<tr>
<td>DA255</td>
<td>1, 1.0</td>
</tr>
<tr>
<td>OMAP1510</td>
<td></td>
</tr>
<tr>
<td>OMAP5910</td>
<td></td>
</tr>
<tr>
<td>P2</td>
<td></td>
</tr>
<tr>
<td>P2+</td>
<td></td>
</tr>
</tbody>
</table>

Device core is not an actual device but is used as a way of indicating that the code is to be generated for a particular revision of the C55x core CPU. For a device not listed above, you must determine which C55x core is used on the device and then use the appropriate −vcore:REV option. −vcore:0 may be used to generate code for the C55x hardware specification; that is, no silicon-specific exceptions need be accounted for.

**Note: Compiling For P2 Reserved Mode Using the −vP2 Option**

When compiling for P2 reserved mode using the −vP2 option, algebraic assembly code is used for both compiler output and inline assembly. The generated code includes workarounds for silicon exceptions in both P2 and P2+ reserved modes. When compiling for P2 reserved mode using −vP2+, only P2+ silicon exception workarounds are included. A separate run-time library, rts552.lib, is provided for P2 and P2+ reserved mode silicon devices.
2.3.3 Symbolic Debugging and Profiling Options

Following are options used to select symbolic debugging or profiling:

- **-g** or **--symdebug:dwarf**
  Generates directives that are used by the C/C++ source-level debugger and enables assembly source debugging in the assembler. The `-g` option disables many code generator optimizations, because they disrupt the debugger. You can use the `-g` option with the `-o` option to maximize the amount of optimization that is compatible with debugging (see section 3.8, *Debugging Optimized Code*, on page 3-14.

  For more information on the DWARF debug format, see the *DWARF Debugging Information Format Specification*, 1992–1993, UNIX International, Inc.

- **--profile:breakpt**
  Disables optimizations that would cause incorrect behavior when using a breakpoint-based profiler.

- **--profile:power**
  Enables power profiling which produces instrument code for the power profiler.

- **--symdebug:none**
  Disables all symbolic debugging output. This option is not recommended; it prevents debugging and most performance analysis capabilities.

- **--symdebug:skeletal**
  Generates as much symbolic debugging information as possible without hindering optimization. Generally, this consists of global-scope information only. This option reflects the default behavior of the compiler.

See section 2.3.9 on page 2-30 for deprecated symbolic debugging options.
2.3.4 Specifying Filenames

The input files that you specify on the command line can be C/C++ source files, assembly source files, or object files. The shell uses filename extensions to determine the file type.

<table>
<thead>
<tr>
<th>Extension</th>
<th>File Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>.c</td>
<td>C source</td>
</tr>
<tr>
<td>.C,.cpp,.cxx, or .cc†</td>
<td>C++ source</td>
</tr>
<tr>
<td>.asm,.abs, or .s* (extension begins with s)</td>
<td>Assembly source</td>
</tr>
<tr>
<td>.obj</td>
<td>Object</td>
</tr>
</tbody>
</table>

† Case sensitivity in filename extensions is determined by your operating system. If your operating system is not case sensitive, .C is interpreted as a C file.

The conventions for filename extensions allow you to compile C and C++ files and assemble assembly files with a single command.

For information about how you can alter the way that the compiler interprets individual filenames, see section 2.3.5. For information about how you can alter the way that the compiler interprets and names the extensions of assembly source and object files, see section 2.3.6.

You can use wildcard characters to compile or assemble multiple files. Wildcard specifications vary by system; use the appropriate form listed in your operating system manual. For example, to compile all of the C files in a directory, enter the following:

```
c155 *.c
```

2.3.5 Changing How the Compiler Interprets Filenames (−fa, −fc, −fg, −fo, and −fp Options)

You can use options to change how the compiler interprets your filenames. If the extensions that you use are different from those recognized by the compiler, you can use the −fa, −fc, −fo, and −fp options to specify the type of file. You can insert an optional space between the option and the filename. Select the appropriate option for the type of file you want to specify:

−fa=filename for an assembly language source file
−fc=filename for a C source file
−fo=filename for an object file
−fp=filename for a C++ source file
Changing the Compiler’s Behavior With Options

For example, if you have a C source file called file.s and an assembly language source file called asmbly, use the \texttt{−fa} and \texttt{−fc} options to force the correct interpretation:

\texttt{cl55 \ −fc=file.s \ −fa=asmbly}

You cannot use the \texttt{−f} options with wildcard specifications.

The \texttt{−fg} option causes the compiler to process C files as \texttt{C++} files. By default, the compiler treats files with a .c extension as C files. See section 2.3.4 on page 2-24 for more information about filename extension conventions.

2.3.6 Changing How the Compiler Interprets and Names Extensions (\texttt{−ea}, \texttt{−ec}, \texttt{−eo}, \texttt{−ep}, and \texttt{−es} Options)

You can use options to change how the compiler interprets filename extensions and names the extensions of the files that it creates. On the command line, these options must precede any filenames to which they apply. You can use wildcard specifications with these options.

Select the appropriate option for the type of extension you want to specify:

\texttt{−ea=ext} for an assembly source file
\texttt{−ec=ext} for a C source file
\texttt{−eo=ext} for an object file
\texttt{−ep=ext} for a \texttt{C++} source file
\texttt{−es=ext} for an assembly listing file

An extension can be up to nine characters in length.

The following example assembles the file fit.rrr and creates an object file named fit.o:

\texttt{cl55 \ −ea\ .rrr \ −eo\ .o \ fit.rrr}
2.3.7 Specifying Directories

By default, the compiler places the object, assembly, and temporary files that it creates into the current directory. If you want the compiler to place these files in different directories, use the following options:

−fbdirectory Specifies the destination directory for absolute listing files. The default is to use the same directory as the object file. To specify a listing file directory, type the directory’s pathname on the command line after the -fb option:

```
c155 -fb d:\object ...
```

−ffdirectory Specifies the destination directory for assembly listing and cross-reference listing files. The default is to use the same directory as the object file directory. Using this option without the assembly listing (-al) option or cross-reference listing (-ax) option will cause the shell to act as if the -al option was specified. To specify a listing file directory, type the directory’s pathname on the command line after the -ff option:

```
c155 -ff d:\object ...
```

−frdirectory Specifies a directory for object files. To specify an object file directory, type the directory’s pathname on the command line after the -fr option:

```
c155 -fr d:\object ...
```

−fsdirectory Specifies a directory for assembly files. To specify an assembly file directory, type the directory’s pathname on the command line after the -fs option:

```
c155 -fs d:\assembly ...
```

−ftdirectory Specifies a directory for temporary intermediate files. To specify a temporary directory, insert the directory’s pathname on the command line after the -ft option:

```
c155 -ft d:\temp ...
```
2.3.8 Options That Control the Assembler

Following are assembler options that you can use with the compiler:

- **−aa**
  Invokes the assembler with the −a assembler option, which creates an absolute listing. An absolute listing shows the absolute addresses of the object code.

- **−ac**
  Makes case insignificant in the assembly language source files. For example, −c makes the symbols ABC and abc equivalent. If you do not use this option, case is significant (this is the default).

- **−ad name**
  −ad name [=value] sets the name symbol. This is equivalent to inserting name .set [value] at the beginning of the assembly file. If value is omitted, the symbol is set to 1.

- **−ahc filename**
  Invokes the assembler with the −hc option, which copies the specified file for the assembly module. The file is inserted before source file statements. The copied file appears in the assembly listing files.

- **−ahi filename**
  Invokes the assembler with the −hi option, which includes the specified file for the assembly module. The file is included before source file statements. The included file does not appear in the assembly listing files.

- **−al**
  (lowercase L) Invokes the assembler with the −l assembler option to produce an assembly listing file.

- **−apd**
  Performs preprocessing for assembly files, but instead of writing preprocessed output, writes a list of dependency lines suitable for input to a standard make utility. The list is written to a file with the same name as the source file but with a .ppa extension.

- **−api**
  Performs preprocessing for assembly files, but instead of writing preprocessed output, writes a list of files included with the #include directive. The list is written to a file with the same name as the source file but with a .ppa extension.

- **−arnum**
  Suppresses the assembler remark identified by num. A remark is an informational assembler message that is less severe than a warning. If you do not specify a value for num, all remarks will be suppressed.
Invokes the assembler with the `−s` assembler option to put labels in the symbol table. Label definitions are written to the COFF symbol table for use with symbolic debugging.

(ARMS mode) Informs the assembler that the ARMS status bit is enabled during the execution of this source file. By default, the assembler assumes that the bit is disabled.

Causes the assembler to treat parallel bus conflict errors as warnings.

(CPL mode) Informs the assembler that the CPL status bit is enabled during the execution of this source file. This causes the assembler to enforce the use of SP-relative addressing syntax. By default, the assembler assumes that the bit is disabled.

Causes the assembler to generate faster code rather than smaller code when porting your C54x files. By default, the assembler tries to encode for small code size.

(C54x compatibility mode) Informs the assembler that the C54CM status bit is enabled during the execution of this source file. By default, the assembler assumes that the bit is disabled.

Causes the assembler to remove NOPs located in the delay slots of C54x delayed branch/call instructions.

Generates assembly instruction profile file with an extension of .prf. The contents of the file are usage counts for each kind of instruction used in the assembly code.

(Mnemonic assembly only). Loosens the requirement that a literal shift count operand begin with a `#` character. This provides compatibility with early versions of the mnemonic assembler. When this option is used and the `#` is omitted, a warning is issued advising you to change to the new syntax.

Informs the assembler that the SST status bit is disabled during the execution of this ported C54x source file. By default, the assembler assumes that the bit is enabled.
Changing the Compiler’s Behavior With Options

−atv Causes the assembler to use the largest (P24) form of certain variable-length instructions. By default, the assembler tries to resolve all variable-length instructions to their smallest size.

−atw (algebraic assembly only) Suppresses assembler warning messages.

−auname Undefines the predefined constant name, which overrides any −ad options for the specified constant.

−aw Enables pipeline conflict warnings.

−ax Causes the assembler to produce a symbolic cross-reference in the listing file.

--purecirc Informs the assembler that the C54x file uses C54x circular addressing (does not use the C55x linear/circular mode bits).

For more information about the assembler, see the TMS320C55x Assembly Language Tools User’s Guide.
2.3.9 Deprecated Options

Several compiler options have been deprecated. The compiler continues to accept these options, but they are not recommended for use. Future releases of the tools will not support these options. Table 2–2 lists the deprecated options and a description of each.

Table 2–2. Compiler Backwards-Compatibility Options Summary

<table>
<thead>
<tr>
<th>Option</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>−gp †</td>
<td>Allows function-level profiling of optimized code</td>
</tr>
<tr>
<td>−gpp‡</td>
<td>Enables power profiling</td>
</tr>
<tr>
<td>−gt</td>
<td>Enables symbolic debugging using the alternate STABS debugging format (equivalent to −−symdebug:coff)</td>
</tr>
<tr>
<td>−gw†</td>
<td>Enables symbolic debugging using the DWARF debugging format</td>
</tr>
<tr>
<td>−−symdebug:coff</td>
<td>Enables symbolic debugging using the alternate STABS debugging format (equivalent to −gt). This option may be necessary to allow debugging with older debuggers or custom tools, which do not read the DWARF format.</td>
</tr>
<tr>
<td>−−symdebug:profile_coff</td>
<td>Enables function-level profiling of optimized code with symbolic debugging using the alternate STABS debugging format</td>
</tr>
</tbody>
</table>

† Replaced by the −−symdebug:dwarf option.
‡ Replaced by −−profile:power option
2.4 Using Environment Variables

You can define environment variables that set certain software tool parameters you normally use. An environment variable is a special system symbol that you define and associate to a string in your system initialization file. The compiler uses this symbol to find or obtain certain types of information.

When you use environment variables, default values are set, making each individual invocation of the compiler simpler because these parameters are automatically specified. When you invoke a tool, you can use command-line options to override many of the defaults that are set with environment variables.

2.4.1 Specifying Directories (C_DIR and C55X_C_DIR)

The compiler uses the C55X_C_DIR and C_DIR environment variables to name alternate directories that contain #include files. The compiler looks for the C55X_C_DIR environment variable first and then reads and processes it. If it does not find this variable, it reads the C_DIR environment variable and processes it. To specify directories for #include files, set C_DIR with one of these commands.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Enter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows™</td>
<td>set C_DIR=<code>directory1[;directory2 ...]</code></td>
</tr>
<tr>
<td>UNIX (Bourne shell)</td>
<td>C_DIR=&quot;directory1 [directory2 ...]&quot;; export C_DIR</td>
</tr>
</tbody>
</table>

The environment variable remains set until you reboot the system or reset the variable.

2.4.2 Setting Default Compiler Options (C_OPTION and C55X_C_OPTION)

You might find it useful to set the compiler, assembler, and linker default options using the C55X_C_OPTION or C_OPTION environment variable. If you do this, the compiler uses the default options and/or input filenames that you name with these variables every time you run the compiler.

Setting the default options with the C_OPTION environment variables is useful when you want to run the compiler consecutive times with the same set of options and/or input files. After the compiler reads the command line and the input filenames, it looks for the C55X_C_OPTION environment variable first and then reads and processes it. If it does not find the C55X_C_OPTION, it reads the C_OPTION environment variable and processes it.
The table below shows how to set C_OPTION the environment variables. Select the command for your operating system:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Enter</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIX (Bourne shell)</td>
<td><code>C_OPTION=&quot;option1 [option2 ...]&quot;; export C_OPTION</code></td>
</tr>
<tr>
<td>Windows</td>
<td><code>set C_OPTION=option1[:option2 ...]</code></td>
</tr>
</tbody>
</table>

Environment variable options are specified in the same way and have the same meaning as they do on the command line. For example, if you want to always run quietly (the −q option), enable C/C++ source interlisting (the −s option), and link (the −z option) for Windows, set up the C_OPTION environment variable as follows:

```
set C_OPTION=−q −s −z
```

In the following examples, each time you run the compiler, it runs the linker. Any options following −z on the command line or in C_OPTION are passed to the linker. This enables you to use the C_OPTION environment variable to specify default compiler and linker options and then specify additional compiler and linker options on the command line. If you have set −z in the environment variable and want to compile only, use the −c option of the compiler. These additional examples assume C_OPTION is set as shown above:

```
cl55*.c               ; compiles and links
cl55−c *.c            ; only compiles
cl55*.c −z lnk.cmd    ; compiles/links using .cmd file
cl55−c *.c −z lnk.cmd ; only compiles (−c overrides −z)
```

For more information about compiler options, see section 2.3, Changing the Compiler’s Behavior With Options, on page 2-5. For more information about linker options, see section 4.2, Linker Options, on page 4-5.
2.5 Controlling the Preprocessor

This section describes specific features that control the C55x preprocessor, which is part of the parser. A general description of C preprocessing is presented in section A12 of K&R. The C55x C/C++ compiler includes standard C/C++ preprocessing functions, which are built into the first pass of the compiler. The preprocessor handles:

- Macro definitions and expansions
- #include files
- Conditional compilation
- Various other preprocessor directives (specified in the source file as lines beginning with the # character)

The preprocessor produces self-explanatory error messages. The line number and the filename where the error occurred are printed along with a diagnostic message.

2.5.1 Predefined Macro Names

The compiler maintains and recognizes the predefined macro names listed in Table 2–3.

Table 2–3. Predefined Macro Names

<table>
<thead>
<tr>
<th>Macro Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>TMS320C55X</em></td>
<td>Always defined</td>
</tr>
<tr>
<td><strong>DATE</strong>†</td>
<td>Expands to the compilation date in the form mm dd yyyy</td>
</tr>
<tr>
<td><strong>FILE</strong>†</td>
<td>Expands to the current source filename</td>
</tr>
<tr>
<td><strong>LARGE_MODEL</strong></td>
<td>Expands to 1 when the −ml compiler option is specified; otherwise, it is undefined</td>
</tr>
<tr>
<td><strong>LINE</strong>†</td>
<td>Expands to the current line number</td>
</tr>
<tr>
<td><strong>TIME</strong>†</td>
<td>Expands to the compilation time in the form hh:mm:ss</td>
</tr>
<tr>
<td><strong>TI_COMPILER_VERSION</strong></td>
<td>Expands to an integer value representing the current compiler version number. For example, version 1.20 is represented as 0012000.</td>
</tr>
<tr>
<td><strong>INLINE</strong></td>
<td>Expands to 1 if optimization is used; undefined otherwise. Regardless of any optimization, always undefined when −pi is used.</td>
</tr>
</tbody>
</table>

† Specified by the ANSI/ISO standard
You can use the names listed in Table 2–3 in the same manner as any other defined name. For example,

```c
printf ( "%s %s" , __TIME__ , __DATE__);
```

translates to a line such as:

```c
printf ("%s %s", "13:58:17", "Jan 14 1999");
```

### 2.5.2 The Search Path for #include Files

The #include preprocessor directive tells the compiler to read source statements from another file. When specifying the file, you can enclose the filename in double quotes or in angle brackets. The filename can be a complete pathname, partial path information, or a filename with no path information.

- If you enclose the filename in double quotes (" "), the compiler searches for the file in the following directories in this order:
  1) The directory that contains the current source file. The current source file refers to the file that is being compiled when the compiler encounters the #include directive.
  2) Directories named with the -I option
  3) Directories set with the C55X_C_DIR or C_DIR environment variables

- If you enclose the filename in angle brackets (< >), the compiler searches for the file in the following directories in this order:
  1) Directories named with the -I option
  2) Directories set with the C55X_C_DIR or C_DIR environment variables

See section 2.5.2.1, Changing the #include File Search Path With the -I Option, for information on using the -I option. For information on how to use the C_DIR environment variable, see section 2.4.1, Specifying Directories (C_DIR and C55X_C_DIR).
2.5.2.1 Changing the #include File Search Path With the −I Option

The −I option names an alternate directory that contains #include files. The format of the −I option is:

−I directory1 [−I directory2 ...]

Each −I option names one directory. In C/C++ source, you can use the #include directive without specifying any directory information for the file; instead, you can specify the directory information with the −I option. For example, assume that a file called source.c is in the current directory. The file source.c contains the following directive statement:

#include "alt.h"

Assume that the complete pathname for alt.h is:

Windows c:\tools\files\alt.h
UNIX /tools/files/alt.h

The table below shows how to invoke the compiler. Select the command for your operating system:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Enter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>cl55 -Ic:\tools\files source.c</td>
</tr>
<tr>
<td>UNIX</td>
<td>cl55 -I/tools/files source.c</td>
</tr>
</tbody>
</table>

2.5.3 Generating a Preprocessed Listing File (−ppo Option)

The −ppo option allows you to generate a preprocessed version of your source file. The preprocessed file has the same name as the source file but with a .pp extension. The compiler’s preprocessing functions perform the following operations on the source file:

- Each source line ending in a backslash (\) is joined with the following line.
- Trigraph sequences are expanded.
- Comments are removed.
- #include files are copied into the file.
- Macro definitions are processed.
- All macros are expanded.
- All other preprocessing directives, including #line directives and conditional compilation, are expanded.
### 2.5.4 Continuing Compilation After Preprocessing (−ppa Option)

If you are preprocessing, the preprocessor performs preprocessing only. By default, it does not compile your source code. If you want to override this feature and continue to compile after your source code is preprocessed, use the −ppa option along with the other preprocessing options. For example, use −ppa with −ppo to perform preprocessing, write preprocessed output to a file with a .pp extension, and then compile your source code.

### 2.5.5 Generating a Preprocessed Listing File With Comments (−ppc Option)

The −ppc option performs all of the preprocessing functions except removing comments and generates a preprocessed version of your source file with a .pp extension. Use the −ppc option instead of the −ppo option if you want to keep the comments.

### 2.5.6 Generating a Preprocessed Listing File With Line-Control Information (−ppl Option)

By default, the preprocessed output file contains no preprocessor directives. If you want to include the #line directives, use the −ppl option. The −ppl option performs preprocessing only and writes preprocessed output with line-control information (#line directives) to a file with the same name as the source file but with a .pp extension.

### 2.5.7 Generating Preprocessed Output for a Make Utility (−ppd Option)

The −ppd option performs preprocessing only, but instead of writing preprocessed output, writes a list of dependency lines suitable for input to a standard make utility. The list is written to a file with the same name as the source file but with a .pp extension. Optionally, you can specify a filename for the output, for example:

```bash
c155 −ppd=make.pp file.c
```

### 2.5.8 Generating a List of Files Included With the #include Directive (−ppi Option)

The −ppi option performs preprocessing only, but instead of writing preprocessed output, writes a list of files included with the #include directive. The list is written to a file with the same name as the source file but with a .pp extension. Optionally, you can specify a filename for the output, for example:

```bash
c155 −ppi=include.pp file.c
```
2.6 Understanding Diagnostic Messages

One of the compiler’s primary functions is to report diagnostics for the source program. When the compiler detects a suspect condition, it displays a message in the following format:

“file.c”, line n: diagnostic severity: diagnostic message

- **file.c**: The name of the file involved
- **line n**: The line number where the diagnostic applies
- **diagnostic severity**: The severity of the diagnostic message (a description of each severity category follows)
- **diagnostic message**: The text that describes the problem

Diagnostic messages have an associated severity, as follows:

- A **fatal error** indicates a problem of such severity that the compilation cannot continue. Examples of problems that can cause a fatal error include command-line errors, internal errors, and missing include files. If multiple source files are being compiled, any source files after the current one will not be compiled.

- An **error** indicates a violation of the syntax or semantic rules of the C/C++ language. Compilation continues, but object code is not generated.

- A **warning** indicates something that is valid but questionable. Compilation continues and object code is generated (if no errors are detected).

- A **remark** is less serious than a warning. It indicates something that is valid and probably intended, but may need to be checked. Compilation continues and object code is generated (if no errors are detected). By default, remarks are not issued. Use the -pdr compiler option to enable remarks.

Diagnostics are written to standard error with a form like the following example:

“test.c”, line 5: error: a break statement may only be used within a loop or switch
    break;
               ^

By default, the source line is omitted. Use the -pdv compiler option to enable the display of the source line and the error position. The above example makes use of this option.

The message identifies the file and line involved in the diagnostic, and the source line itself (with the position indicated by the ^ symbol) follows the message. If several diagnostics apply to one source line, each diagnostic has the form shown; the text of the source line is displayed several times, with an appropriate position indicated each time.
Understanding Diagnostic Messages

Long messages are wrapped to additional lines, when necessary.

You can use a command-line option (−pden) to request that the diagnostic’s numeric identifier be included in the diagnostic message. When displayed, the diagnostic identifier also indicates whether the diagnostic can have its severity overridden on the command line. If the severity can be overridden, the diagnostic identifier includes the suffix −D (for discretionary); otherwise, no suffix is present. For example:

"Test_name.c", line 7: error #64−D: declaration does not declare anything
  struct {}; ^

"Test_name.c", line 9: error #77: this declaration has no storage class or type specifier
  xxxxx; ^

Because an error is determined to be discretionary based on the error severity associated with a specific context, an error can be discretionary in some cases and not in others. All warnings and remarks are discretionary.

For some messages, a list of entities (functions, local variables, source files, etc.) is useful; the entities are listed following the initial error message:

"test.c", line 4: error: more than one instance of overloaded function “f” matches the argument list:
  function “f(int)”
  function “f(float)”
  argument types are: (double)
  f(1.5); ^

In some cases, additional context information is provided. Specifically, the context information is useful when the front end issues a diagnostic while doing a template instantiation or while generating a constructor, destructor, or assignment operator function. For example:

"test.c", line 7: error: “A::A()” is inaccessible
  B x;
  ^
  detected during implicit generation of “B::B()” at line 7

Without the context information, it is difficult to determine to what code the error refers.
2.6.1 Controlling Diagnostics

The compiler provides diagnostic options that allow you to modify how the parser interprets your code. You can use these options to control diagnostics:

−pdel=\textit{num} \quad \text{Sets the error limit to } \textit{num}, \text{ which can be any decimal value. The compiler abandons compiling after this number of errors. (The default is 100.)}

−pdem \quad \text{Displays a diagnostic's numeric identifier along with its text. Use this option in determining which arguments you need to supply to the diagnostic suppression options (−pds, −pdse, −pdsr, and −pdsw).}

This option also indicates whether a diagnostic is discretionary. A discretionary diagnostic is one whose severity can be overridden. A discretionary diagnostic includes the suffix −D; otherwise, no suffix is present. See section 2.6, Understanding Diagnostic Messages, for more information.

−pdf \quad \text{Produces diagnostics information file with the same name as the corresponding source file but with an } .err \text{ extension.}

−pdr \quad \text{Issues remarks (nonserious warnings), which are suppressed by default.}

−pds=\textit{num} \quad \text{Suppresses the diagnostic identified by } \textit{num}. \text{ To determine the numeric identifier of a diagnostic message, use the −pdem option first in a separate compile. Then use −pdsn to suppress the diagnostic. You can suppress only discretionary diagnostics.}

−pdse=\textit{num} \quad \text{Categorizes the diagnostic identified by } \textit{num} \text{ as an error. To determine the numeric identifier of a diagnostic message, use the −pdem option first in a separate compile. Then use −pdse=\textit{num} to recategorize the diagnostic as an error. You can alter the severity of discretionary diagnostics only.}

−pdsr=\textit{num} \quad \text{Categorizes the diagnostic identified by } \textit{num} \text{ as a remark. To determine the numeric identifier of a diagnostic message, use the −pdem option first in a separate compile. Then use −pdsr=\textit{num} to recategorize the diagnostic as a remark. You can alter the severity of discretionary diagnostics only.}

−pdsw=\textit{num} \quad \text{Categorizes the diagnostic identified by } \textit{num} \text{ as a warning. To determine the numeric identifier of a diagnostic message, use the −pdem option first in a separate compile. Then use −pdsw=\textit{num} to recategorize the diagnostic as a warning. You can alter the severity of discretionary diagnostics only.}
−pdv Provides verbose diagnostics that display the original source with line-wrap and indicate the position of the error in the source line.

−pdw Suppresses warning diagnostics (errors are still issued).

2.6.2 How You Can Use Diagnostic Suppression Options

The following example demonstrates how you can control diagnostic messages issued by the compiler.

Consider the following code segment:

```c
int one();
int i;
int main()
{
    switch (i) {
        case 1:
            return one();
            break;
        default:
            return 0;
            break;
    }
}
```

If you invoke the compiler with the −q option, this is the result:

```
"err.c", line 9: warning: statement is unreachable
"err.c", line 12: warning: statement is unreachable
```

Because it is standard programming practice to include break statements at the end of each case arm to avoid the fall-through condition, these warnings can be ignored. Using the −pdem option, you can find out the diagnostic identifier for these warnings. Here is the result:

```
[err.c]
"err.c", line 9: warning #112-D: statement is unreachable
"err.c", line 12: warning #112-D: statement is unreachable
```

Next, you can use the diagnostic identifier of 112 as the argument to the −pdsr option to treat this warning as a remark. This compilation now produces no diagnostic messages (because remarks are disabled by default).

Although this type of control is useful, it can also be extremely dangerous. The compiler often emits messages that indicate a less than obvious problem. Be careful to analyze all diagnostics emitted before using the suppression options.
2.6.3 Other Messages

Other error messages that are unrelated to the source, such as incorrect command-line syntax or inability to find specified files, are usually fatal. They are identified by one of the strings “>> WARNING:” or “>> ERROR:” preceding the message.

For example:

```bash
cl55 -j
>> WARNING: invalid option -j (ignored)
>> ERROR: no source files
```
2.7 Generating Cross-Reference Listing Information (−px Option)

The −px shell option generates a cross-reference listing file (.crl) that contains reference information for each identifier in the source file. (The −px option is separate from −ax, which is an assembler rather than a compiler option.) The information in the cross-reference listing file is displayed in the following format:

\[
\begin{array}{cccc}
\text{sym-id} & \text{name} & \text{X} & \text{filename} \quad \text{line number} \quad \text{column number} \\
\end{array}
\]

- **sym-id**: An integer uniquely assigned to each identifier
- **name**: The identifier name
- **X**: One of the following values:
  - D: Definition
  - d: Declaration (not a definition)
  - M: Modification
  - A: Address taken
  - U: Used
  - C: Changed (used and modified in a single operation)
  - R: Any other kind of reference
  - E: Error; reference is indeterminate
- **filename**: The source file
- **line number**: The line number in the source file
- **column number**: The column number in the source file
2.8 Generating a Raw Listing File (−pl Option)

The −pl option generates a raw listing file (.rl) that can help you understand how the compiler is preprocessing your source file. Whereas the preprocessed listing file (generated with the −ppo, −ppc, and −ppl preprocessor options) shows a preprocessed version of your source file, a raw listing file provides a comparison between the original source line and the preprocessed output. The raw listing file contains the following information:

- Each original source line
- Transitions into and out of include files
- Diagnostics
- Preprocessed source line if nontrivial processing was performed (comment removal is considered trivial; other preprocessing is nontrivial)

Each source line in the raw listing file begins with one of the identifiers listed in Table 2–4.

**Table 2–4. Raw Listing File Identifiers**

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>N</td>
<td>Normal line of source</td>
</tr>
<tr>
<td>X</td>
<td>Expanded line of source. It appears immediately following the normal line of source if nontrivial preprocessing occurs.</td>
</tr>
<tr>
<td>S</td>
<td>Skipped source line (false #if clause)</td>
</tr>
<tr>
<td>L</td>
<td>Change in source position, given in the following format:</td>
</tr>
<tr>
<td></td>
<td>L line number filename key</td>
</tr>
<tr>
<td></td>
<td>Where line number is the line number in the source file. The key is present only when the change is due to entry/exit of an include file. Possible values of key are as follows:</td>
</tr>
<tr>
<td></td>
<td>1 = entry into an include file</td>
</tr>
<tr>
<td></td>
<td>2 = exit from an include file</td>
</tr>
</tbody>
</table>

The −pl option also includes diagnostic identifiers as defined in Table 2–5.

**Table 2–5. Raw Listing File Diagnostic Identifiers**

<table>
<thead>
<tr>
<th>Diagnostic identifier</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>E</td>
<td>Error</td>
</tr>
<tr>
<td>F</td>
<td>Fatal</td>
</tr>
<tr>
<td>R</td>
<td>Remark</td>
</tr>
<tr>
<td>W</td>
<td>Warning</td>
</tr>
</tbody>
</table>
Diagnostic raw listing information is displayed in the following format:

```
S  filename  line number  column number  diagnostic
```

- **S**: One of the identifiers in Table 2-5 that indicates the severity of the diagnostic
- **filename**: The source file
- **line number**: The line number in the source file
- **column number**: The column number in the source file
- **diagnostic**: The message text for the diagnostic

Diagnostics after the end of file are indicated as the last line of the file with a column number of 0. When diagnostic message text requires more than one line, each subsequent line contains the same file, line, and column information but uses a lowercase version of the diagnostic identifier. For more information about diagnostic messages, see section 2.6, *Understanding Diagnostic Messages*. 
2.9 Using Inline Function Expansion

When an inline function is called, the C source code for the function is inserted at the point of the call. This is known as inline function expansion. Inline function expansion is advantageous in short functions for the following reasons:

- It saves the overhead of a function call.
- Once inlined, the optimizer is free to optimize the function in context with the surrounding code.

There are several types of inline function expansion:

- Inlining with intrinsic operators (intrinsics are always inlined)
- Automatic inlining
- Definition-controlled inlining with the unguarded inline keyword
- Definition-controlled inlining with the guarded inline keyword

**Note:** Function Inlining Can Greatly Increase Code Size

Expanding functions inline expands code size, especially inlining a function that is called in a number of places. Function inlining is optimal for functions that are called only from a small number of places and for small functions.

2.9.1 Inlining Intrinsic Operators

There are many intrinsic operators for the C55x. The compiler replaces intrinsic operators with efficient code (usually one instruction). This inlining happens automatically whether or not you use the optimizer.

For details about intrinsics, and a list of the intrinsics, see section 6.5.4, *Using Intrinsics to Access Assembly Language Statements*, on page 6-28.

Additional functions that may be expanded inline are:

- abs
- labs
- fabs
- assert
- _nassert
- memcpy

2.9.2 Automatic Inlining

When compiling C/C++ source code with the −O3 option, inline function expansion is performed on small functions. For more information, see section 3.6, *Automatic Inline Expansion (−oi Option)*, on page 3-11.
2.9.3 Unguarded Definition-Controlled Inlining

The inline keyword specifies that a function is expanded inline at the point at which it is called rather than by using standard calling procedures. The compiler performs inline expansion of functions declared with the inline keyword.

You must invoke the optimizer with any −o option (−O0, −O1, −O2, or −O3) to turn on definition-controlled inlining. Automatic inlining is also turned on when using −O3.

The following example shows usage of the inline keyword, where the function call is replaced by the code in the called function.

Example 2−1. Using the inline Keyword

```
inline float volume_sphere(float r)
{
    return 4.0/3.0 * PI * r * r * r;
}
int foo(...)
{
    ...
    volume = volume_sphere(radius);
    ...
}
```

The −pi option turns off definition-controlled inlining. This option is useful when you need a certain level of optimization but do not want definition-controlled inlining.

2.9.4 Guarded Inlining and the _INLINE Preprocessor Symbol

When declaring a function in a header file as static inline, additional procedures should be followed to avoid a potential code size increase when inlining is turned off with −pi or the optimizer is not run.

In order to prevent a static inline function in a header file from causing an increase in code size when inlining gets turned off, use the following procedure. This allows external-linkage when inlining is turned off; thus, only one function definition will exist throughout the object files.

- Prototype a static inline version of the function. Then, prototype an alternative, nonstatic, externally-linked version of the function. Conditionally preprocess these two prototypes with the _INLINE preprocessor symbol, as shown in Example 2−2.

- Create an identical version of the function definition in a .c or .cpp file, as shown in Example 2−2.
In Example 2−2 there are two definitions of the strlen function. The first, in the header file, is an inline definition. This definition is enabled and the prototype is declared as static inline only if _INLINE is true (_INLINE is automatically defined for you when the optimizer is used and −pi is not specified).

The second definition, for the library, ensures that the callable version of strlen exists when inlining is disabled. Since this is not an inline function, the _INLINE preprocessor symbol is undefined (#undef) before string.h is included to generate a noninline version of strlen’s prototype.

Example 2−2. How the Run-Time-Support Library Uses the _INLINE Preprocessor Symbol

(a) string.h

```c
#ifndef _SIZE_T
#define _SIZE_T
typedef unsigned int size_t;
#endif
#ifdef _INLINE
#define __INLINE static inline
#else
#define __INLINE
#endif
__INLINE size_t strlen(const char * _string);

#ifdef _INLINE
/*******************************************************************************/
/* strlen                                                                   */
/*******************************************************************************/
static inline size_t strlen(const char *string)
{
    size_t n = (size_t) -1;
    const char *s = string - 1;
    do n++; while (*++s);
    return n;
}
#endif
#endif
```
Using Inline Function Expansion

Example 2–2. How the Run-Time-Support Library Uses the _INLINE Preprocessor Symbol (Continued)

(b) strlen.c

```c
/****************************************************************************
/* strlen v x.xx                                                          */
/* Copyright (c) 2002 Texas Instruments Incorporated                      */
/****************************************************************************
#undef _INLINE
#include <string.h>
size_t strlen(const char *string)
{
  size_t n = (size_t) -1;
  const char *s = string - 1;
  do n++; while (*++s);
  return n;
}
```

2.9.5 Inlining Restrictions

There are several restrictions on what functions can be inlined for both automatic inlining and definition-controlled inlining. Functions with local static variables or a variable number of arguments are not inlined, with the exception of functions declared as static inline. In functions declared as static inline, expansion occurs despite the presence of local static variables. In addition, a limit is placed on the depth of inlining for recursive or nonleaf functions. Furthermore, inlining should only be used for small functions or functions that are called in a few places (though the compiler does not enforce this).

A function may be disqualified from inlining if it:

- Returns a struct or union
- Has a struct or union parameter
- Has a volatile parameter
- Has a variable length argument list
- Declares a struct, union, or enum type
- Contains a static variable
- Contains a volatile variable
- Is recursive
- Contains a pragma
- Has too large of a stack (too many local variables)
2.10 Using Interlist

The compiler tools allow you to interlist C/C++ source statements into the assembly language output of the compiler. Interlisting enables you to inspect the assembly code generated for each C/C++ statement. Interlisting behaves differently, depending on whether or not the optimizer is used, and depending on which options you specify.

The easiest way to invoke the interlisting feature is to use the −ss option. To compile and run interlist on a program called function.c, enter:

c155 −ss function.c

The −ss option prevents the shell from deleting the interlisted assembly language output file. The output assembly file, function.asm, is assembled normally.

When you invoke interlisting without the optimizer, interlist runs as a separate pass between the code generator and the assembler. It reads both the assembly and C/C++ source files, merges them, and writes the C/C++ statements into the assembly file as comments.

Example 2–3 shows a typical interlisted assembly file. For more information about using interlist with the optimizer, see section 3.7, Using Interlist With the Optimizer, on page 3-12.
Using Interlist

Example 2–3. An Interlisted Assembly Language File

```assembly
.global _main
;-----------------------------------------------
; 3 | void main (void)
;-----------------------------------------------
;*************************************************************************
;* FUNCTION NAME : _main *
;* Stack Frame : Compact (No Frame Pointer, w/ debug) *
;* Total Frame Size : 3 words *
;* (1 return address/alignment) *
;* (2 function parameters) *
;*************************************************************************

_main:
AADD #−3, SP
;-----------------------------------------------
; 5 | printf("Hello World\n");
;-----------------------------------------------

MOV #SL1, *SP(#0)
CALL #_printf ; call occurs [#_printf];
AADD #3, SP
RET ; return occurs

;*************************************************************************
;* STRINGS                                                              *
;*************************************************************************
.sect ".const"
.align 1
SL1: .string "Hello World",10,0

;*************************************************************************
;* UNDEFINED EXTERNAL REFERENCES                                        *
;*************************************************************************
.global _printf
```
The compiler tools include an optimization program that improves the execution speed and reduces the size of C/C++ programs by performing such tasks as simplifying loops, rearranging statements and expressions, and allocating variables into registers.

This chapter describes how to invoke the optimizer and describes which optimizations are performed when you use it. This chapter also describes how you can use the interlist feature with the optimizer and how you can profile or debug optimized code.

3.1 Invoking Optimization

The C/C++ compiler is able to perform various optimizations. High-level optimizations are performed in the optimizer, which must be used to achieve optimal code.

The easiest way to invoke optimization is to specify the −on option on the cl55 command line. The n denotes the level of optimization (0, 1, 2, and 3), which controls the type and degree of optimization:

- **−O0**
  - Performs control-flow-graph simplification
  - Allocates variables to registers
  - Performs loop rotation
  - Eliminates unused code
  - Simplifies expressions and statements
  - Expands calls to functions declared inline

- **−O1**
  Performs all −O0 optimizations, plus:
  - Performs local copy/constant propagation
  - Removes unused assignments
  - Eliminates local common expressions

- **−O2**
  Performs all −O1 optimizations, plus:
  - Performs loop optimizations
  - Eliminates global common subexpressions
  - Eliminates global unused assignments
  - Performs loop unrolling

The optimizer uses −O2 as the default if you use −o without an optimization level.

- **−O3**
  Performs all −O2 optimizations, plus:
  - Removes all functions that are never called
  - Simplifies functions with return values that are never used
  - Inlines calls to small functions
  - Reorders function declarations so that the attributes of called functions are known when the caller is optimized
  - Identifies file-level variable characteristics

If you use −O3, see section 3.2, Performing File-Level Optimization (−O3 Option, on page 3-3 for more information.
The levels of optimization described above are performed by the stand-alone optimization pass. The code generator performs several additional optimizations, particularly processor-specific optimizations; it does so regardless of whether you invoke the optimizer. These optimizations are always enabled although they are much more effective when the optimizer is used.

### 3.2 Performing File-Level Optimization (−O3 Option)

The −O3 option instructs the compiler to perform file-level optimization. You can use the −O3 option alone to perform general file-level optimization, or you can combine it with other options to perform more specific optimization. The options listed in Table 3–1 work with −O3 to perform the indicated optimization:

**Table 3–1. Options That You Can Use With −O3**

<table>
<thead>
<tr>
<th>If you ...</th>
<th>Use this option</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>Have files that redeclare standard library functions</td>
<td>−oln</td>
<td>3-3</td>
</tr>
<tr>
<td>Want to create an optimization information file</td>
<td>−onn</td>
<td>3-4</td>
</tr>
<tr>
<td>Want to compile multiple source files</td>
<td>−pm</td>
<td>3-5</td>
</tr>
</tbody>
</table>

### 3.2.1 Controlling File-Level Optimization (−ol Option)

When you invoke optimization with the −O3 option, some of the optimizations use known properties of the standard library functions. If your file redeclares any of these standard library functions, these optimizations become ineffective. The −ol option (lowercase L) controls file-level optimizations. The number following −ol denotes the level (0, 1, or 2). Use Table 3–2 to select the appropriate level to append to the −ol option.

**Table 3–2. Selecting a Level for the −ol Option**

<table>
<thead>
<tr>
<th>If your source file ...</th>
<th>Use this option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Declares a function with the same name as a standard library function and alters it</td>
<td>−ol0</td>
</tr>
<tr>
<td>Contains definitions of library functions that are identical to the standard library functions; does not alter functions declared in the standard library</td>
<td>−ol1</td>
</tr>
<tr>
<td>Does not alter standard library functions, but you used the −ol0 or the −ol1 option in a command file or an environment variable. The −ol2 option restores the default behavior of the optimizer.</td>
<td>−ol2</td>
</tr>
</tbody>
</table>
3.2.2 Creating an Optimization Information File (−on Option)

When you invoke optimization with the −O3 option, you can use the −on option to create an optimization information file that you can read. The number following the −on denotes the level (0, 1, or 2). The resulting file has an .nfo extension. Use Table 3–3 to select the appropriate level to append to the −on option.

Table 3–3. Selecting a Level for the −on Option

<table>
<thead>
<tr>
<th>If you …</th>
<th>Use this option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Do not want to produce an information file, but you used the −on1 or −on2 option in a command file or an environment variable. The −on0 option restores the default behavior of the optimizer.</td>
<td>−on0</td>
</tr>
<tr>
<td>Want to produce an optimization information file</td>
<td>−on1</td>
</tr>
<tr>
<td>Want to produce a verbose optimization information file</td>
<td>−on2</td>
</tr>
</tbody>
</table>
3.3 Performing Program-Level Optimization (−pm and −O3 Options)

You can specify program-level optimization by using the −pm option with the −O3 option. With program-level optimization, all of your source files are compiled into one intermediate file called a module. The module moves to the optimization and code generation passes of the compiler. Because the compiler can see the entire program, it performs several optimizations that are rarely applied during file-level optimization:

- If a particular argument in a function always has the same value, the compiler replaces the argument with the value and passes the value instead of the argument.
- If a return value of a function is never used, the compiler deletes the return code in the function.
- If a function is not called directly or indirectly by main, the compiler removes the function.

To see which program-level optimizations the compiler is applying, use the −on2 option to generate an information file. See section 3.2.2, Creating an Optimization Information File (−on Option), on page 3-4 for more information.

3.3.1 Controlling Program-Level Optimization (−op Option)

You can control program-level optimization, which you invoke with −pm −O3, by using the −op option. Specifically, the −op option indicates if functions in other modules can call a module’s external functions or modify the module’s external variables. The number following −op indicates the level you set for the module that you are allowing to be called or modified. The −O3 option combines this information with its own file-level analysis to decide whether to treat this module’s external function and variable declarations as if they had been declared static. Use Table 3–4 to select the appropriate level to append to the −op option.
Performing Program-Level Optimization (−pm and −O3 Options)

Table 3–4. Selecting a Level for the −op Option

<table>
<thead>
<tr>
<th>If your module …</th>
<th>Use this option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Has functions that are called from other modules and global variables that are modified in other modules</td>
<td>−op0</td>
</tr>
<tr>
<td>Does not have functions that are called by other modules but has global variables that are modified in other modules</td>
<td>−op1</td>
</tr>
<tr>
<td>Does not have functions that are called by other modules or global variables that are in other modules</td>
<td>−op2</td>
</tr>
<tr>
<td>Has functions that are called from other modules but does not have global variables that are modified in other modules</td>
<td>−op3</td>
</tr>
</tbody>
</table>

In certain circumstances, the compiler reverts to a different −op level from the one you specified, or it might disable program-level optimization altogether. Table 3–5 lists the combinations of −op levels and conditions that cause the compiler to revert to other −op levels.

Table 3–5. Special Considerations When Using the −op Option

<table>
<thead>
<tr>
<th>If your −op is…</th>
<th>Under these conditions</th>
<th>Then the −op level</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not specified</td>
<td>The −O3 optimization level was specified.</td>

<tr>
<td>−op1 or −op2</td>
<td>No functions are identified by the FUNC_EXT_CALLED pragma.</td>
<td>Reverts to −op0</td>
</tr>
<tr>
<td>−op3</td>
<td>Any condition</td>
<td>Remains −op3</td>
</tr>
</tbody>
</table>

In some situations when you use −pm and −O3, you must use an −op options or the FUNC_EXT_CALLED pragma. See section 3.3.2, Optimization Considerations When Mixing C and Assembly, on page 3-7 for information about these situations.
3.3.2 Optimization Considerations When Mixing C and Assembly

If you have any assembly functions in your program, you need to exercise caution when using the –pm option. The compiler recognizes only the C/C++ source code and not any assembly code that might be present. Because the compiler does not recognize the assembly code calls and variable modifications to C/C++ functions, the –pm option optimizes out those C/C++ functions. To keep these functions, place the FUNC_EXT_CALLED pragma (see section 5.7.7, The FUNC_EXT_CALLEDPragma, on page 5-24) before any declaration or reference to a function that you want to keep.

Another approach you can take when you use assembly functions in your program is to use the –op option with the –pm and –O3 options (see section 3.3.1, Controlling Program-Level Optimization, on page 3-5).

In general, you achieve the best results through judicious use of the FUNC_EXT_CALLED pragma in combination with –pm –O3 and –op1 or –op2.

If any of the following situations apply to your application, use the suggested solution:

Situation: Your application consists of C/C++ source code that calls assembly functions. Those assembly functions do not call any C/C++ functions or modify any C/C++ variables.

Solution: Compile with –pm –O3 –op2 to tell the compiler that outside functions do not call C/C++ functions or modify C/C++ variables. See section 3.3.1 for information about the –op2 option.

If you compile with the –pm –O3 options only, the compiler reverts from the default optimization level (–op2) to –op0. The compiler uses –op0, because it presumes that the calls to the assembly language functions that have a definition in C/C++ may call other C/C++ functions or modify C/C++ variables.

Situation: Your application consists of C/C++ source code that calls assembly functions. The assembly language functions do not call C/C++ functions, but they modify C/C++ variables.

Solution: Try both of these solutions and choose the one that works best with your code:

- Compile with –pm –O3 –op1
- Add the volatile keyword to those variables that may be modified by the assembly functions and compile with –pm –O3 –op2. (See section 5.4.6, The volatile Keyword, page 5-14, for more information.)

See section 3.3.1 for information about the –op option.
Performing Program-Level Optimization (−pm and −O3 Options)

**Situation**
Your application consists of C source code and assembly source code. The assembly functions are interrupt service routines that call C functions; the C functions that the assembly functions call are never called from C. These C functions act like main: they function as entry points into C.

**Solution**
Add the volatile keyword to the C variables that may be modified by the interrupts. Then, you can optimize your code in one of these ways:

- You achieve the best optimization by applying the FUNC_EXT_CALLED pragma to all of the entry-point functions called from the assembly language interrupts, and then compiling with −pm −O3 −op2. *Ensure that you use the pragma with all of the entry-point functions.* If you do not, the compiler removes the entry-point functions that are not preceded by the FUNC_EXT_CALL pragma.

- Compile with −pm −O3 −op3. Because you do not use the FUNC_EXT_CALL pragma, you must use the −op3 option, which is less aggressive than the −op2 option, and your optimization may not be as effective.

Keep in mind that if you use −pm −O3 without additional options, the compiler removes the C functions that the assembly functions call. Use the FUNC_EXT_CALLED pragma to keep these functions.

See section 5.7.7 on page 5-24 for information about the FUNC_EXT_CALLED pragma and section 3.3.1 for information about the −op option.
3.4 Using Caution With asm Statements in Optimized Code

You must be extremely careful when using asm (inline assembly) statements in optimized code. The optimizer rearranges code segments, uses registers freely, and may completely remove variables or expressions. Although the compiler never optimizes out an asm statement (except when it is totally unreachable), the surrounding environment where the assembly code is inserted can differ significantly from the original C/C++ source code.

It is usually safe to use asm statements to manipulate hardware controls such as interrupt masks, but asm statements that attempt to interface with the C/C++ environment or access C/C++ variables can have unexpected results. After compilation, check the assembly output to make sure your asm statements are correct and maintain the integrity of the program.
3.5 Accessing Aliased Variables in Optimized Code

Aliasing occurs when a single object can be accessed in more than one way, such as when two pointers point to the same object or when a pointer points to a named object. Aliasing can disrupt optimization, because any indirect reference can refer to another object. The compiler analyzes the code to determine where aliasing can and cannot occur, then optimizes as much as possible while still preserving the correctness of the program. The compiler behaves conservatively. If there is a chance that two pointers are pointing at the same object, then the compiler assumes that the pointers do point to the same object.

The compiler assumes that any variable whose address is passed as an argument to a function is not subsequently modified by an alias set up in the called function. Examples include:

- Returning the address from a function
- Assigning the address to a global variable

If you use aliases like this, you must use the −ma shell option when you are optimizing your code. For example, if your code is similar to this, use the −ma option:

```c
int *glob_ptr;

int *f(int *arg)
{
    glob_ptr = arg;
    return arg;
}
```

```c
int *g() {
    int x = 1;
    int *p = f(&x);
    *p = 5;    /* p aliases x */
    *glob_ptr = 10;   /* glob_ptr aliases x */
    h(x);
}
```
3.6 Automatic Inline Expansion (−oi Option)

When optimizing with the −O3 option, the compiler automatically inlines small functions. The −oisize option specifies the size threshold. Any function larger than the size threshold is not automatically inlined. You can use the −oisize option in the following ways:

- If you set the size parameter to 0 (−oi0), automatic inline expansion is disabled.
- If you set the size parameter to a nonzero integer, the compiler uses the size threshold as a limit to the size of the functions it automatically inlines. The optimizer multiplies the number of times the function is inlined (plus 1 if the function is externally visible and its declaration cannot be safely removed) by the size of the function.

The compiler inlines the function only if the result is less than the size parameter. The compiler measures the size of a function in arbitrary units; however, the optimizer information file (created with the −on1 or −on2 option) reports the size of each function in the same units that the −oi option uses.

The −oisize option controls only the inlining of functions that are not explicitly declared as inline. If you do not use the −oi option, the compiler inlines very small functions.

Note: −O3 Optimization and Inlining

In order to turn on automatic inlining, you must use the −O3 option. The −O3 option turns on other optimizations. If you desire the −O3 optimizations, but not automatic inlining, use −oi0 with the −O3 option.

Note: Inlining and Code Size

Expanding functions inline increases code size, especially inlining a function that is called in a number of places. Function inlining is optimal for functions that are called only from a small number of places and for small functions. In order to prevent increases in code size because of inlining, use the −oi0 and −pi options. These options cause the compiler to inline intrinsics only.
3.7 Using Interlist With Optimization

You control the output of the interlist feature when compiling with optimization (the \(-O_n\) option) with the \(-os\) and \(-ss\) options.

- The \(-os\) option interlists compiler comments with assembly source statements.

- The \(-ss\) and \(-os\) options together interlist the compiler comments and the original C/C++ source with the assembly code.

When you use the \(-os\) option with optimization, the interlist feature does not run as a separate pass. Instead, the optimizer inserts comments into the code, indicating how the optimizer has rearranged and optimized the code. These comments appear in the assembly language file as comments starting with `**`. The C/C++ source code is not interlisted unless you use the \(-ss\) option also.

The interlist feature can affect optimized code because it might prevent some optimization from crossing C/C++ statement boundaries. Optimization makes normal source interlisting impractical, because the compiler extensively rearranges your program. Therefore, when you use the \(-os\) option, the optimizer writes reconstructed C/C++ statements. These statements may not reflect the exact C/C++ syntax of the operation being performed.

Example 3–1 shows the function from Example 2–3 on page 2-50 compiled with optimization (\(-O2\)) and the \(-os\) option. The assembly file contains compiler comments interlisted with assembly code.

**Example 3–1. The Function From Example 2–3 Compiled With the \(-O2\) and \(-os\) Options**

```
_main:
;** 5  ------------------ printf((char *)"Hello, world\n");
;** 5  ------------------ return;
AADD #−3, SP
MOV #SL1, *SP(#0)
CALL #_printf
; call occurs [#_printf]
AADD #3, SP
RET ;return occurs
```
When you use the −ss and −os options with optimization, the compiler inserts its comments and the interlist feature runs before the assembler, merging the original C/C++ source into the assembly file.

Example 3–2 shows the function from Example 2–3 on page 2-50 compiled with optimization (−O2) and the −ss and −os options. The assembly file contains compiler comments and C source interlisted with assembly code.

Example 3–2. The Function From Example 2–3 Compiled With the −O2, −os, and −ss Options

```
_main:
;; 5  ---------------  printf((char *)"Hello, world\n");
;; 5  ---------------  return;
    AADD #−3, SP
;; ---------------------------------------------------
;  5  printf("Hello, world\n");
;---------------------------------------------------
    MOV #SL1, *SP(#0)
    CALL #_printf
        ; call occurs [#_printf]
    AADD #3, SP
    RET          ;return occurs
```

Note: Impact on Performance and Code Size

The −ss option can have a negative effect on performance and code size.
3.8 Debugging Optimized Code

Debugging fully optimized code is not recommended, because the compiler’s extensive rearrangement of code and the many-to-many allocation of variables to registers often make it difficult to correlate source code with object code. Profiling code that has been built with the --symdebug:dwarf (or -g) option or the --symdebug:coff option (STABS debug) is not recommended as well, because these options can significantly degrade performance. To remedy these problems, you can use the options described in the following sections to optimize your code in such a way that you can still debug or profile the code.

3.8.1 Debugging Optimized Code (--g, --symdebug:dwarf, --symdebug:coff, and -O Options)

To debug optimized code, use the -o option in conjunction with one of the symbolic debugging options (--symdebug:dwarf or --symdebug:coff). The symbolic debugging options generate directives that are used by the C/C++ source-level debugger, but they disable many compiler optimizations. When you use the -O option (which invokes optimization) with the --symdebug:dwarf or --symdebug:coff option, you turn on the maximum amount of optimization that is compatible with debugging.

If you want to use symbolic debugging and still generate fully optimized code, use the --mn option. The --mn option reenables the optimizations disabled by --symdebug:dwarf or --symdebug:coff. However, if you use the --mn option, portions of the debugger’s functionality will be unreliable.

Note: Symbolic Debugging Options Affect Performance and Code Size

Using the --symdebug:dwarf or --symdebug:coff option can cause a significant performance and code size degradation of your code. Use these options for debugging only. Using --symdebug:dwarf or --symdebug:coff when profiling is not recommended.
3.8.2 Profiling Optimized Code

To profile optimized code, use optimization (−O0 through −O3) without debugging. Not using symbolic debugging allows you to profile optimized code at the granularity of functions.

If you have a breakpoint-based profiler, use the −−profile:breakpt option with the −O option. The −−profile:breakpt option disables optimizations that would cause incorrect behavior when using a breakpoint-based profiler.

If you have a power profiler, use the −−profile:power option with the −O option. The −−profile:power option produces instrument code for the power profiler.

If you need to profile code at a finer grain that the function level in Code Composer Studio, you can use the −−symdebug:dwarf, or −−symdebug:coff option, although this is not recommended. You might see a significant performance degradation because the compiler cannot use all optimizations with debugging. It is recommended that outside of Code Composer Studio, you use the clock( ) function.

**Note: Profile Points**

In Code Composer Studio, when symbolic debugging is not used, profile points can only be set at the beginning and end of functions.
3.9 What Kind of Optimization Is Being Performed?

The TMS320C55x C/C++ compiler uses a variety of optimization techniques to improve the execution speed of your C/C++ programs and to reduce their size. Optimization occurs at various levels throughout the compiler.

Most of the optimizations described here are performed by the separate optimizer pass that you enable and control with the −o compiler options (see section 3.1 on page 3-2). However, the code generator performs some optimizations that you cannot selectively enable or disable.

Following is a small sample of the optimizations performed by the compiler.

3.9.1 Cost-Based Register Allocation

The compiler, when enabled with optimization, allocates registers to user variables and compiler temporary values according to their type, use, and frequency. Variables used within loops are weighted to have priority over others, and those variables whose uses don’t overlap can be allocated to the same register.

3.9.2 Alias Disambiguation

C/C++ programs generally use many pointer variables. Frequently, compilers are unable to determine whether or not two or more symbols, pointer references, or structure references refer to the same memory location. This aliasing of memory locations often prevents the compiler from retaining values in registers because it cannot be sure that the register and memory continue to hold the same values over time.

Alias disambiguation is a technique that determines when two pointer expressions cannot point to the same location, allowing the compiler to freely optimize such expressions.

3.9.3 Branch Optimizations and Control-Flow Simplification

The compiler analyzes the branching behavior of a program and rearranges the linear sequences of operations (basic blocks) to remove branches or redundant conditions. Unreachable code is deleted, branches to branches are bypassed, and conditional branches over unconditional branches are simplified to a single conditional branch.

When the value of a condition is determined at compile time (through copy propagation or other data flow analysis), the compiler can delete a conditional branch. Switch case lists are analyzed in the same way as conditional branches and are sometimes eliminated entirely. Some simple control flow constructs can be reduced to conditional instructions, totally eliminating the need for a branch.
What Kind of Optimization Is Being Performed?

In Example 3–3, the switch statement and the state variable from this simple finite state machine example are optimized completely away, leaving a streamlined series of conditional branches.

Example 3–3. Control-Flow Simplification and Copy Propagation

(a) C source

```c
fsm()
{
    enum { ALPHA, BETA, GAMMA, OMEGA } state = ALPHA;
    int  *input;

    while (state != OMEGA)
        switch (state)
        {
            case ALPHA: state = (*input++ == 0) ? BETA: GAMMA; break;
            case BETA : state = (*input++ == 0) ? GAMMA: ALPHA; break;
            case GAMMA: state = (*input++ == 0) ? GAMMA: OMEGA; break;
        }
}
```

(b) C compiler output

```
; opt55 -O3 control.if control.opt
;*****************************************************************************
;* FUNCTION NAME: _fsm                                                       *
;*****************************************************************************
_fsm:                             
    MOV *AR3+, AR1
    BCC L2, AR1=!#0
L1:                               
    MOV *AR3+, AR1
    BCC L2, AR1==#0
    MOV *AR3+, AR1
    BCC L1, AR1==#0
L2:                               
    MOV *AR3+,AR1
    BCC L2, AR1==#0
    RET
```
3.9.4 Data Flow Optimizations

Collectively, the following data flow optimizations replace expressions with less costly ones, detect and remove unnecessary assignments, and avoid operations that produce values that are already computed. The optimizer performs these data flow optimizations both locally (within basic blocks) and globally (across entire functions).

- **Copy propagation**
  Following an assignment to a variable, the compiler replaces references to the variable with its value. The value can be another variable, a constant, or a common subexpression. This can result in increased opportunities for constant folding, common subexpression elimination, or even total elimination of the variable. See Example 3−3 on page 3-18 and Example 3−4 on page 3-20.

- **Common subexpression elimination**
  When two or more expressions produce the same value, the compiler computes the value once, saves it, and reuses it.

- **Redundant assignment elimination**
  Often, copy propagation and common subexpression elimination optimizations result in unnecessary assignments to variables (variables with no subsequent reference before another assignment or before the end of the function). The optimizer removes these dead assignments (see Example 3−4).

3.9.5 Expression Simplification

For optimal evaluation, the compiler simplifies expressions into equivalent forms, requiring fewer instructions or registers. Operations between constants are folded into single constants. For example, \( a = (b + 4) - (c + 1) \) becomes \( a = b - c + 3 \).

In Example 3−4, the constant 3, assigned to a, is copy propagated to all uses of a; a becomes a dead variable and is eliminated. The sum of multiplying \( j \) by 3 plus multiplying \( j \) by 2 is simplified into \( b = j \times 5 \). The assignments to a and b are eliminated.
Example 3–4. Data Flow Optimizations and Expression Simplification

(a) C source

```c
char simplify(char j)
{
    char a = 3;
    char b = (j*a) + (j*2);
    return b;
}
```

(b) C compiler output

```c
; opt55 -O2 data.if data.opt
;***********************************************************
;* FUNCTION NAME: _simplify                             *
;***********************************************************
_simplify:
    MOV T0, HI(AC0)
    MPYK #5,AC0,AC0
    MOV AC0, T0
    RET
```
3.9.6 Inline Expansion of Functions

The compiler replaces calls to small functions with inline code, saving the overhead associated with a function call as well as providing increased opportunities to apply other optimizations (see Example 3−5).

In Example 3−5, the compiler finds the code for the C function `plus()` and replaces the call with the code.

**Example 3−5. Inline Function Expansion**

(a) C source

```c
static int plus (int x, int y)
{
    return x + y;
}

int main ()
{
    int a = 3;
    int b = 4;
    int c = 5;
    return plus (a, plus (b, c));
}
```

(b) C compiler output

```assembly
; opt55 -O3 inline.if inline.opt

.sect " .text"
.global _main
;***********************************************************
;* FUNCTION NAME: _main                                    *
;***********************************************************
_main:
    MOV #12,T0
    RET
```
3.9.7 Induction Variables and Strength Reduction

Induction variables are variables whose value within a loop is directly related to the number of executions of the loop. Array indices and control variables of for loops are very often induction variables.

Strength reduction is the process of replacing inefficient expressions involving induction variables with more efficient expressions. For example, code that indexes into a sequence of array elements is replaced with code that increments a pointer through the array.

Induction variable analysis and strength reduction together often remove all references to your loop control variable, allowing its elimination entirely.

3.9.8 Loop-Invariant Code Motion

This optimization identifies expressions within loops that always compute the same value. The computation is moved in front of the loop, and each occurrence of the expression in the loop is replaced by a reference to the precomputed value.

3.9.9 Loop Rotation

The compiler evaluates loop conditionals at the bottom of loops, saving an extra branch out of the loop. In many cases, the initial entry conditional check and the branch are optimized out.

3.9.10 Autoincrement Addressing

For pointer expressions of the form \( *p++ \), the compiler uses efficient C55x autoincrement addressing modes. In many cases, where code steps through an array in a loop such as:

```
for (i = 0; i < N; ++i) a[i]...
```

the loop optimizations convert the array references to indirect references through autoincremented register variable pointers (see Example 3–6).

This optimization is designed especially for the C55x architecture. It does not apply to general C code since it works on the sections of code that apply only to the device.
Example 3–6. Autoincrement Addressing, Loop Invariant Code Motion, and Strength Reduction

(a) C source

```c
int a[10], b[10];
void scale(int k)
{
    int i;
    for (i = 0; i < 10; ++i)
        a[i] = b[i] * k;
}
```

(b) C compiler output

```assembly
;**********************************************************************
;* FUNCTION NAME: _scale                                          *
;**********************************************************************
_scale:
   MOV #(_b & 0xffff), AR2
   MOV #(_a & 0xffff), AR3
   MOV #9, BRC0
   RPTBLOCAL L2-1
   MPYM *AR2+, T0, AC0
   MOV AC0, *AR3+
L2:
   RET
```

3.9.11 Repeat Blocks

The C55x supports zero-overhead loops with the RPTB (repeat block) instruction. With the optimizer, the compiler can detect loops controlled by counters and generate them using the efficient repeat forms. The iteration count can be either a constant or an expression.

Induction variable elimination and loop test replacement allow the compiler to recognize the loop as a simple counting loop and then generate a repeat block. Strength reduction turns the array references into efficient pointer autoincrements.
3.9.12 Tail Merging

If you are optimizing for code size, tail merging can be very effective for some functions. Tail merging finds basic blocks that end in an identical sequence of instructions and have a common destination. If such a set of blocks is found, the sequence of identical instructions is made into its own block. These instructions are then removed from the set of blocks and replaced with branches to the newly created block. Thus, there is only one copy of the sequence of instructions, rather than one for each block in the set.

Example 3–7. Tail Merging

(a) C source

```c
int main(int a)
{
    if (a < 0)
    {
        a = -a;
        a += f(a)*3;
    }
    else if (a == 0)
    {
        a = g(a);
        a += f(a)*3;
    }
    else
    a += f(a);

    return a;
}
```
(b) C compiler output

```c
_main:
    push (DR2)
    DR2 = AR1
    if (DR2>=#0) goto L3
    AC0 = DR2
    AC0 = −AC0
    goto L6
L3:
    if (DR2==#0) goto L5
    AR1 = DR2
    call #_f
    AR1 = AC0
    DR2 = DR2 + AR1
    goto L7
L5:
    AR1 = DR2
    call #_g
L6:
    DR2 = AC0
    AR1 = DR2
    call #_f
    DR1 = AC0
    AC0 = DR2
    AC0 = AC0 + (DR1 * #3)
    DR2 = AC0
L7:
    AC0 = DR2
    DR2 = pop()
    return
```
The TMS320C55x™ C/C++ compiler and assembly language tools provide two methods for linking your programs:

- You can compile individual modules and then link them together. This method is especially useful when you have multiple source files.
- You can compile and link in one step. This method is useful when you have a single source module.

This chapter describes how to invoke the linker with each method. It also discusses special requirements of linking C/C++ code, including the run-time-support libraries, specifying the initialization model, and allocating the program into memory. For a complete description of the linker, see the TMS320C55x Assembly Language Tools User’s Guide.

4.1 Invoking the Linker (−z Option)

This section explains how to invoke the linker after you have compiled and assembled your programs: as a separate step or as part of the compile step.

4.1.1 Invoking the Linker As a Separate Step

This is the general syntax for linking C/C++ programs as a separate step:

```
cl55 −z {−c|−cr} filenames [options] [−o name.out] [lnk.cmd] −l library
```

- **cl55 −z** The command that invokes the linker
- **−c | −cr** Options that tell the linker to use special conventions defined by the C/C++ environment. When you use cl55 −z, you must use −c or −cr. The −c option uses automatic variable initialization at run time; the −cr option uses automatic variable initialization at load time.
- **filenames** Names of object files, linker command files, or archive libraries. The default extension for all input files is .obj; any other extension must be explicitly specified. The linker can determine whether the input file is an object or ASCII file that contains linker commands. The default output filename is a.out, unless you use the −o option to name the output file.
- **options** Options affect how the linker handles your object files. Linker options can only appear after the −z option on the command line but may otherwise be in any order. (Options are discussed in section 4.2, Linker Options.)
- **−o name.out** The −o option names the output file.
- **lnk.cmd** Contains options, filenames, directives, or commands for the linker.
- **−l libraryname** (lowercase L) Identifies the appropriate archive library containing C/C++ run-time-support and floating-point math functions. (The −l option tells the linker that a file is an archive library.) You can use the libraries included with the compiler, or you can create your own run-time-support library. If you have specified a run-time-support library in a linker command file, you do not need this parameter.
When you specify a library as linker input, the linker includes and links only those library members that resolve undefined references.

The linker uses a default allocation algorithm to allocate your program into memory. You can use the MEMORY and SECTIONS directives in the linker command file to customize the allocation process. For more information, see the TMS320C55x Assembly Language Tools User’s Guide.

You can link a C/C++ program consisting of modules prog1.obj, prog2.obj, and prog3.obj with an executable filename of prog.out with the command:

```sh
cl55 -z -c prog1 prog2 prog3 -o prog.out -l rts55.lib
```

### 4.1.2 Invoking the Linker As Part of the Compile Step

This is the general syntax for linking C/C++ programs as part of the compile step:

```
cl55 [options] filenames -z (-c|-cr) filenames [options] [-o name.out] -l library [ink.cmd]
```

The `-z` option divides the command line into the compiler options (the options before `-z`) and the linker options (the options following `-z`). The `-z` option must follow all source files and compiler options on the command line.

All arguments that follow `-z` on the command line are passed to the linker. These arguments can be linker command files, additional object files, linker options, or libraries. These arguments are the same as described in section 4.1.1, *Invoking the Linker As a Separate Step*, on page 4-2.

All arguments that precede `-z` on the command line are compiler arguments. These arguments can be C/C++ source files, assembly files, or compiler options. For a description of these arguments, see section 2.2, *Invoking the C/C++ Compiler*, on page 2-4.

You can compile and link a C/C++ program consisting of modules prog1.c, prog2.c, and prog3.c, with an executable filename of prog.out with the command:

```sh
cl55 prog1.c prog2.c prog3.c -z -c -o prog.out -l rts55.lib
```
Note: Order of Processing Arguments in the Linker

The order in which the linker processes arguments is important. The compiler passes arguments to the linker in the following order:

1) Object filenames from the command line
2) Arguments following the −z option on the command line
3) Arguments following the −z option from the C_OPTION or C55X_C_OPTION environment variable

4.1.3 Disabling the Linker (−c Option)

You can override the −z option by using the −c option. The −c option is especially helpful if you specify the −z option in the C_OPTION or C55X_C_OPTION environment variable and want to selectively disable linking with the −c option on the command line.

The −c linker option has a different function than, and is independent of, the compiler’s −c option. By default, the compiler uses the −c linker option when you use the −z option. This tells the linker to use C/C++ linking conventions (autoinitialization of variables at run time). If you want to autoinitialize variables at load time, use the −cr linker option following the −z option.
4.2 Linker Options

All command-line input following the −z option is passed to the linker as parameters and options. Following are the options that control the linker, along with detailed descriptions of their effects:

−a

Produces an absolute, executable module. This is the default; if neither −a nor −r is specified, the linker acts as if −a is specified.

−abs

Produces an absolute listing file. You must use the −O option (after −z) to specify the .out file for the absolute lister, even if you use a linker command file that already uses −O.

−ar

Produces a relocatable, executable object module

−−args=size

Allocates memory to be used by the loader to pass arguments from the command line of the loader to the program. The linker allocates size bytes in an uninitialized .args section. The __c_args__ symbol contains the address of the .args section.

−b

Disables merge of symbolic debugging information

−c

Autoinitializes variables at run time

−cr

Autoinitializes variables at load time

−e=global_symbol

Defines a global_symbol that specifies the primary entry point for the output module

−f=fill_value

Sets the default fill value for holes within output sections; fill_value is a 16-bit constant

−g=global_symbol

Defines a global_symbol as global even if the global symbol has been made static with the −h linker option

−h

Makes all global symbols static

−heap=size

Sets heap size (for the dynamic memory allocation) to size bytes and defines a global symbol that specifies the heap size. The default is 2000 bytes.

−−help

Displays the help screen of all options and their usage.

−I=directory

Alters the library-search algorithm to look in directory before looking in the default location. This option must appear before the −I linker option. The directory must follow operating system conventions. You can specify up to 128 −I options
Linker Options

- `j` Disables conditional linking
- `k` Ignore alignment flags in input sections
- `l=filename` (lowercase L) Names an archive library file as linker input; `filename` is an archive library name and must follow operating system conventions.
- `m=filename` Produces a map or listing of the input and output sections, including holes, and places the listing in `filename`. The filename must follow operating system conventions.
- `o=filename` Names the executable output module. The `filename` must follow operating system conventions. If the `-o` option is not used, the default filename is `a.out`.
- `priority` Provides an alternate search mechanism for libraries. `-priority` causes each unresolved reference to be satisfied by the first library on the command line that contains a definition for that symbol.
- `q` Requests a quiet run (suppresses the banner)
- `r` Retains relocation entries in the output module
- `s` Strips symbol table information and line number entries from the output module
- `stack=size` Sets the primary C/C++ system stack size to `size` bytes and defines a global symbol that specifies the stack size. The default is 1000 bytes.
- `sysstack size` Sets the secondary system stack size to `size` bytes and defines a global symbol that specifies the secondary stack size. The default is 1000 bytes.
- `u=symbol` Places the unresolved external symbol `symbol` into the output module’s symbol table
- `w` Displays a message when an undefined output section is created
-x Forces rereading of libraries. Resolves back references.

--xml_link_info=file Generates an XML link information file. This option causes the linker to generate a well-formed XML file containing detailed information about the result of a link. The information included in this file includes all of the information that is currently produced in a linker generated map file.

For more information on linker options, see the Linker Description chapter of the TMS320C55x Assembly Language Tools User’s Guide.
4.3 Controlling the Linking Process

Regardless of the method you choose for invoking the linker, special requirements apply when linking C/C++ programs. You must:

- Include the compiler’s run-time-support library
- Specify the initialization model
- Determine how you want to allocate your program into memory

This section discusses how these factors are controlled and provides an example of the standard default linker command file.

For more information about how to operate the linker, see the Linker Description chapter of the TMS320C55x Assembly Language Tools User’s Guide.

4.3.1 Linking With Run-Time-Support Libraries

You must link all C/C++ programs with a run-time-support library. The library contains standard C/C++ functions as well as functions used by the compiler to manage the C/C++ environment. You must use the −l linker option to specify the run-time-support library to use. The −l option also tells the linker to look at the −I options and then the C_DIR environment variable to find an archive path or object file.

To use the −l option, type on the command line:

```
cl55 −z {−c | −cr} filenames −l libraryname
```

Generally, the libraries should be specified as the last filenames on the command line because the linker searches libraries for unresolved references in the order that files are specified on the command line. If any object files follow a library, references from those object files to that library are not resolved. You can use the −x linker option to force the linker to reread all libraries until references are resolved. Wherever you specify a library as linker input, the linker includes and links only those library members that resolve undefined references.
4.3.2 Run-Time Initialization

You must link all C/C++ programs with code to initialize and execute the program called a *bootstrap routine*. The bootstrap routine is responsible for the following tasks:

1) Set up status and configuration registers
2) Set up the stack and secondary system stack
3) Process the .cinit run-time initialization table to autoinitialize global variables (when using the −c option)
4) Call all global object constructors (.pinit)
5) Call main
6) Call exit when main returns

A sample bootstrap routine is _c_int00, provided in boot.obj in rts55.lib. The *entry point* is usually set to the starting address of the bootstrap routine.

Chapter 7, *Run-Time-Support Functions*, describes additional run-time-support functions that are included in the library. These functions include ANSI/ISO C standard run-time support.

---

**Note: The _c_int00 Symbol**

If you use the −c or −cr linker option, _c_int00 is automatically defined as the entry point for the program.

---

4.3.3 Initialization By the Interrupt Vector

If your program begins running from load time, you must set up the reset vector to branch to _c_int00. This causes boot.obj to be loaded from the library and your program is initialized correctly. A sample interrupt vector is provided in vectors.obj in rts55.lib. For C55x, the first few lines of the vector are:

```assembly
.def  _Reset
.ref  _c_int00
_Reset: .ivec _c_int00, USE_RETA
```
4.3.4 Global Object Constructors

Global C++ variables having constructors and destructors require their constructors to be called during program initialization and their destructors to be called during program termination. The C/C++ compiler produces a table of constructors to be called at startup.

The table is contained in a named section called .pinit. The constructors are invoked in the order that they occur in the table.

Global constructors are called after initialization of other global variables and before main() is called. Global destructors are invoked during exit() similarly to functions registered through atexit().

Section 6.9.3, Initialization Tables, on page 6-46 discusses the format of the .pinit table.

4.3.5 Specifying the Type of Initialization

The C/C++ compiler produces data tables for autoinitializing global variables. Section 6.9.3, Initialization Tables, on page 6-46 discusses the format of these tables. These tables are in a named section called .cinit. The initialization tables are used in one of the following ways:

- Autoinitializing variables at run time. Global variables are initialized at run time. Use the −c linker option (see section 6.9.4, Autoinitialization of Variables at Run Time, on page 6-49).

- Initializing variables at load time. Global variables are initialized at load time. Use the −cr linker option (see section 6.9.5, Initialization of Variables at Load Time, on page 6-50).

When you link a C/C++ program, you must use either the −c or the −cr linker option. These options tell the linker to select autoinitialization at run time or load time. When you compile and link programs, the −c linker option is the default; if used, the −c linker option must follow the −z option (see section 4.1, Invoking the Linker (−z Option) on page 4-2). The following list outlines the linking conventions used with −c or −cr:

- The symbol _c_int00 is defined as the program entry point; it identifies the beginning of the C/C++ boot routine in boot.obj. When you use −c or −cr, _c_int00 is automatically referenced; this ensures that boot.obj is automatically linked in from the run-time-support library.

- The .cinit output section is padded with a termination record so that the loader (load-time initialization) or the boot routine (run-time initialization) knows when to stop reading the initialization tables.
When initializing at load time (the `−cr` linker option), the following occur:

- The linker sets the symbol `cinit` to −1. This indicates that the initialization tables are not in memory, so no initialization is performed at run time.

- The `STYP_COPY` flag is set in the `.cinit` section header. `STYP_COPY` is the special attribute that tells the loader to perform autoinitialization directly and not to load the `.cinit` section into memory. The linker does not allocate space in memory for the `.cinit` section.

When autoinitializing at run time (−c linker option), the linker defines the symbol `cinit` as the starting address of the `.cinit` section. The boot routine uses this symbol as the starting point for autoinitialization.

**Note: Boot Loader**

Note that a loader is not included as part of the C/C++ compiler tools. Use the C55x simulator or emulator with the source debugger as a loader.

### 4.3.6 Specifying Where to Allocate Sections in Memory

The compiler produces relocatable blocks of code and data. These blocks, called sections, are allocated into memory in a variety of ways to conform to a variety of system configurations.

The compiler creates two basic kinds of sections: initialized and uninitialized. Table 4−1 summarizes the sections.

**Table 4−1. Sections Created by the Compiler**

<table>
<thead>
<tr>
<th>(a) Initialized sections</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>.cinit</code></td>
<td>Tables for explicitly initialized global and static variables</td>
</tr>
<tr>
<td><code>.const</code></td>
<td>Global and static const variables that are explicitly initialized and string literals</td>
</tr>
<tr>
<td><code>.pinit</code></td>
<td>Tables for global object constructors</td>
</tr>
<tr>
<td><code>.text</code></td>
<td>Executable code</td>
</tr>
<tr>
<td><code>.switch</code></td>
<td>Switch statement tables</td>
</tr>
</tbody>
</table>
### Table 4–1. Sections Created by the Compiler (Continued)

<table>
<thead>
<tr>
<th>Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>.bss</td>
<td>Global and static variables</td>
</tr>
<tr>
<td>.cio</td>
<td>C I/O buffer</td>
</tr>
<tr>
<td>.stack</td>
<td>Primary stack</td>
</tr>
<tr>
<td>.sysstack</td>
<td>Secondary system stack</td>
</tr>
<tr>
<td>.sysmem</td>
<td>Memory for malloc functions</td>
</tr>
</tbody>
</table>

When you link your program, you must specify where to allocate the sections in memory.

**Note: Allocating Sections**

When allocating sections, keep in mind that the .stack and .sysstack sections must be on the same 64K-word data page. Also, only code sections are allowed to cross page boundaries.

In general, initialized sections are linked into ROM or RAM; uninitialized sections are linked into RAM. See section 6.1.4, *Sections*, on page 6-4 for a complete description of how the compiler uses these sections. The linker provides MEMORY and SECTIONS directives for allocating sections. For more information about allocating sections into memory, see the *Linker Description* chapter of the *TMS320C55x Assembly Language Tools User’s Guide*.

#### 4.3.7 A Sample Linker Command File

Example 4–1 shows a typical linker command file that links a C/C++ program. The command file in this example is named lnk.cmd and lists several linker options. To link the program, enter:

```
c155 -z object_file(s) -o outfile -m mapfile lnk.cmd
```

The MEMORY and possibly the SECTIONS directive might require modification to work with your system. See the *Linker Description* chapter of the *TMS320C55x Assembly Language Tools User’s Guide* for information on these directives.
Example 4–1. Linker Command File

```c
-stack 0x2000 /* PRIMARY STACK SIZE */
-sysstack 0x1000 /* SECONDARY STACK SIZE */
-heap 0x2000 /* HEAP AREA SIZE */
-c /* Use C linking conventions: auto-init vars at run time*/
-u _Reset /* Force load of reset interrupt handler */

/* SPECIFY THE SYSTEM MEMORY MAP */
MEMORY
{
  PAGE 0: /* ----- Unified Program/Data Address Space ----- */
      RAM (RWIX): origin = 0x000100, length = 0x01FF00 /* 128Kb page of RAM */
      ROM (RIX) : origin = 0x020100, length = 0x01FF00 /* 128Kb page of ROM */
      VECS (RIX): origin = 0xFFFF00, length = 0x000100 /* 256-byte int vector */
  PAGE 2: /* ------ 64K-word I/O Address Space ------- */
      IOPORT (RWI) : origin = 0x000000, length = 0x020000
}
/* SPECIFY THE SECTIONS ALLOCATION INTO MEMORY */
SECTIONS
{
  .text > ROM PAGE 0 /* CODE */
  /* These sections must be on same physical memory page when */
  /* small memory model is used */
  .data > RAM PAGE 0 /* INITIALIZED VARS */
  .bss > RAM PAGE 0 /* GLOBAL & STATIC VARS */
  .const > RAM PAGE 0 /* CONSTANT DATA */
  .sysmem > RAM PAGE 0 /* DYNAMIC MEMORY (malloc) */
  .stack > RAM PAGE 0 /* PRIMARY SYSTEM STACK */
  .sysstack > RAM PAGE 0 /* SECONDARY SYSTEM STACK */
  .cio > RAM PAGE 0 /* C I/O BUFFERS */
  /* The .switch, .cinit, and .pinit sections may be on any */
  /* physical memory page when small memory model is used */
  .switch > RAM PAGE 0 /* SWITCH STATEMENT TABLES */
  .cinit > RAM PAGE 0 /* AUTOINITIALIZATION TABLES */
  .pinit > RAM PAGE 0 /* INITIALIZATION FN TABLES */
  .vectors > VECS PAGE 0 /* INTERRUPT VECTORS */
  .ioport > IOPORT PAGE 2 /* GLOBAL & STATIC IO VARS */
}
```
The TMS320C55x™ C/C++ compiler supports the C/C++ language standard that was developed by a committee of the International Organization for Standardization (ISO) to standardize the C programming language.

The C++ language supported by the C55x is defined in the ISO/IEC 14882–1998 C++ Standard and described in the *The Annotated C++ Reference Manual* (ARM). In addition, many of the extensions from the ISO/IEC 14882–1998 C++ standard are implemented.

5.1 Characteristics of TMS320C55x C

The ISO standard identifies certain features of the C language that are affected by characteristics of the target processor, run-time environment, or host environment. For reasons of efficiency or practicality, this set of features can differ among standard compilers. This section describes how these features are implemented for the C55x C/C++ compiler.

The following list identifies all such cases and describes the behavior of the C55x C/C++ compiler in each case. Each description also includes a reference to more information. Many of the references are to the formal ISO standard for C or to the second edition of *The C Programming Language* by Kernighan and Ritchie (K&R).

5.1.1 Identifiers and Constants

- All characters of all identifiers are significant. Case is significant; uppercase and lowercase characters are distinct for identifiers. These characteristics apply to all identifiers, internal and external. (ISO 6.1.2, K&R A2.3)
- The source (host) and execution (target) character sets are assumed to be ASCII. There are no multibyte characters. (ISO 5.2.1, K&R A12.1)
- Hex or octal escape sequences in character or string constants may have values up to 32 bits. (ISO 6.1.3.4, K&R A2.5.2)
- Character constants with multiple characters are encoded as the last character in the sequence. For example, ‘abc’ == ‘c’ (ISO 6.1.3.4, K&R A2.5.2)

5.1.2 Data Types

- For information about the representation of data types, see section 5.3. (ISO 6.1.2.5, K&R A4.2)
- The type size_t, which is the result of the sizeof operator, is unsigned int. (ISO 6.3.3.4, K&R A7.4.8)
- The type ptrdiff_t, which is the result of pointer subtraction, is int. (ISO 6.3.6, K&R A7.7)
5.1.3 Conversions

- Float-to-integer conversions truncate toward 0. (ISO 6.2.1.3, K&R A6.3)
- Pointers and integers can be freely converted, as long as the result type is large enough to hold the original value. (ISO 6.3.4, K&R A6.6)

5.1.4 Expressions

- When two signed integers are divided and either is negative, the quotient is negative, and the sign of the remainder is the same as the sign of the numerator. The slash mark (/) is used to find the quotient and the percent symbol (%) is used to find the remainder. For example,
  \[ 10 \div -3 = -3, \quad -10 \div 3 = -3 \]
  \[ 10 \mod -3 = 1, \quad -10 \mod 3 = -1 \] (ISO 6.3.5, K&R A7.6)
- A signed modulus operation takes the sign of the dividend (the first operand).
- A right shift of a signed value is an arithmetic shift; that is, the sign is preserved. (ISO 6.3.7, K&R A7.8)

5.1.5 Declaration

- The register storage class is effective for all chars, shorts, ints, and pointer types. (ISO 6.5.1, K&R A2.1)
- Structure members are packed into words. (ISO 6.5.2.1, K&R A8.3)
- A bit field defined as an integer is signed. Bit fields are packed into words and do not cross word boundaries. (ISO 6.5.2.1, K&R A8.3)
- The interrupt keyword can be applied only to void functions that have no arguments. For more information, see section 5.4.3 on page 5-12. (TI C extension)
5.1.6 Preprocessor

The preprocessor ignores any unsupported #pragma directive.

The following pragmas are supported.

- CODE_SECTION
- C54X_CALL
- C54X_FAR_CALL
- DATA_ALIGN
- DATA_SECTION
- FAR – only used for extaddr.h
- FUNC_CANNOT_INLINE
- FUNC_EXT_CALLED
- FUNC_IS_PURE
- FUNC_IS_SYSTEM
- FUNC_NEVER_RETURNS
- FUNC_NO_GLOBAL_ASG
- FUNC_NO_IND_ASG
- INTERRUPT
- MUST_ITERATE
- UNROLL

For more information on pragmas, see section 5.7 on page 5-17.
5.2 Characteristics of TMS320C55x C++

The C55x compiler supports C++ as defined in the ISO/IEC 14882–1998 C++ standard. The exceptions to the standard are as follows:

☑ Complete C++ standard library support is not included. In particular, the iostream library is not supported. C subset and basic language support is included.

☑ Exception handling is not supported.

☑ Run-time type information (RTTI) is disabled by default. RTTI allows the type of an object to be determined at run time. It can be enabled with the −rtti compiler option.

☑ The only C++ standard library header files included are <typeinfo> and <new>. Support for bad_cast or bad_type_id is not included in the typeinfo header.

☑ The following C++ headers for C library facilities are not included:
  ● <locale>
  ● <csignal>
  ● <cwchar>
  ● <cwctype>

☑ The reinterpret_cast type does not allow casting a pointer-to-member of one class to a pointer-to-member of another class if the classes are unrelated.

☑ Two-phase name binding in templates, as described in [temp.res] and [temp.dep] of the standard, is not implemented.

☑ Template parameters are not implemented.

☑ The export keyword for templates is not implemented.

☑ A partial specialization of a class member template cannot be added outside of the class definition.
5.3 Data Types

Table 5-1 lists the size, representation, and range of each scalar data type or the C55x compiler. Many of the range values are available as standard macros in the header file limits.h. For more information, see section 7.3.6, Limits (float.h and limits.h), on page 7-19.

Note: C55x Byte is 16 Bits

By ISO C definition, the size of operator yields the number of bytes required to store an object. ISO further stipulates that when sizeof is applied to char, the result is 1. Since the C55x char is 16 bits (to make it separately addressable), a byte is also 16 bits. This yields results you may not expect; for example, sizeof (int) == 1 (not 2). C55x bytes and words are equivalent (16 bits).
Note:  long long is 40 bits

The long long data type is implemented according to the ISO/IEC 9899 C Standard. However, the C55x compiler implements this data type as 40 bits instead of 64 bits. Use the "ll" length modifier with formatted I/O functions (such as printf and scanf) to print or read long long variables. For example:

printf("%lld\n", (long long)global);
5.4 Keywords

The C55x C/C++ compiler supports the standard const and volatile keywords. In addition, the C55x C/C++ compiler extends the C/C++ language through the support of the interrupt, ioport, and restrict keywords.

5.4.1 The const Keyword

The C55x C/C++ compiler supports the ISO standard keyword \textit{const}. This keyword gives you greater control over allocation of storage for certain data objects. You can apply the const qualifier to the definition of any variable or array to ensure that their values are not altered.

If you define an object as const, the const section allocates storage for the object. The const data storage allocation rule has two exceptions:

- If the keyword volatile is also specified in the definition of an object (for example, volatile const int \( x \)). Volatile keywords are assumed to be allocated to RAM. (The program does not modify a const volatile object, but something external to the program might.)

- If the object is auto (function scope).

In both cases, the storage for the object is the same as if the const keyword were not used.

The placement of the const keyword within a definition is important. For example, the first statement below defines a constant pointer \( p \) to a variable int. The second statement defines a variable pointer \( q \) to a constant int:

\[
\begin{align*}
\text{int * const } p &= \&x; \\
\text{const int * } q &= \&x;
\end{align*}
\]

Using the const keyword, you can define large constant tables and allocate them into system ROM. For example, to allocate a ROM table, you could use the following definition:

\[
\text{const int digits [ ] } = \{0,1,2,3,4,5,6,7,8,9\};
\]
5.4.2 The ioport Keyword

The C55x processor contains a secondary memory space for I/O. The compiler extends the C/C++ language by adding the ioport (or __ioport) keyword to support the I/O addressing mode.

The ioport type qualifier can be used with the standard type specifiers including arrays, structures, unions, and enumerations. It can also be used with the const and volatile type qualifiers. When used with an array, ioport qualifies the elements of the array, not the array type itself. Members of structures cannot be qualified with ioport unless they are pointers to ioport data.

The ioport type qualifier can only be applied to global or static variables. Local variables cannot be qualified with ioport unless the variable is a pointer declaration. For example:

```c
void foo (void)
{
    ioport int i; /* invalid */
    ioport int *j; /* valid */
}
```

When declaring a pointer qualified with ioport, note that the meaning of the declaration will be different depending on where the qualifier is placed. Because I/O space is 16-bit addressable, pointers to I/O space are always 16 bits, even in the large memory model.

Note that you cannot use printf() with a direct ioport pointer argument. Instead, pointer arguments in printf() must be converted to “void **”, as shown in the example below:

```c
ioport int *p;
printf("%p\n", (void*)p);
```

The declaration shown in Example 5–1 places a pointer in I/O space that points to an object in data memory.

Example 5–1. Declaring a Pointer in I/O Space

(a) C source

```c
int * ioport ioport_pointer; /* ioport pointer */
int i;
int j;

void foo (void)
{
    ioport_pointer = &i;
    j = *ioport_pointer;
}
```
Example 5-1. Declaring a Pointer in I/O Space (Continued)

(b) Compiler output

```
_foo:
    MOV #_i, port(#_ioport_pointer) ; store addr of #i
        ; (I/O memory)
    MOV port(#_ioport_pointer), AR3 ; load address of #i
        ; (I/O memory)
    MOV *AR3, AR1    ; indirectly load value of #i
    MOV AR1, *abs16(#_j) ; store value of #i at #j
RET
```

If typedef had been used in Example 5-1, the pointer declaration would have been:

```c
typedef int *int_pointer;
ioport int_pointer ioport_pointer; /* ioport pointer */
```

Example 5-2 declares a pointer that points to data in I/O space. This pointer is 16 bits even in the large memory model.

Example 5-2. Declaring a Pointer That Points to Data in I/O Space

(a) C source

```c
/* pointer to ioport data: */
ioport int * ptr_to_ioport;
ioport int i;

void foo (void)
{
    int j;
i = 10;
    ptr_to_ioport = &i;
j = *ptr_to_ioport;
}
```

(b) Compiler output

```
_foo:
    MOV #_i,*abs16(#_ptr_to_ioport) ; store address of #i
    MOV *abs16(#_ptr_to_ioport),AR3
    AADD #1, SP
    MOV #10,port(#_i)    ; store 10 at #i (I/O memory)
    MOV *AR3, AR1
    MOV AR1, *SP(#0)
    AADD #1, SP
RET
```
Example 5–3 declares an ioport pointer that points to data in I/O space.

Example 5–3. Declaring an ioport Pointer That Points to Data in I/O Space

(a) C source

```c
/* ioport pointer to ioport data: */
ioport int * ioport iop_ptr_to_ioport;
ioport int i;
ioport int j;

void foo (void)
{
i = 10;
ioport_ptr_to_ioport = &i;
j = *ioport_ptr_to_ioport;
}
```

(b) Compiler output

```assembly
_foo:
    MOV #10, port(#_i) ; store 10 at #i (I/O memory)
    MOV #_i, port(#_ioport_ptr_to_ioport); store address of
     ; #i (I/O memory)
    MOV port(#_ioport_ptr_to_ioport), AR3 ; load addr of #i
    MOV *AR3, AR1 ; load #i
    MOV AR1, port(#_j) ; store 10 in #j (I/O memory)
    RET
```
5.4.3 The interrupt Keyword

The C55x compiler extends the C/C++ language by adding the interrupt (or \_\_interrupt) keyword to specify that a function is to be treated as an interrupt function.

Functions that handle interrupts require special register saving rules and a special return sequence. When C/C++ code is interrupted, the interrupt routine must preserve the contents of all machine registers that are used by the routine or by any function called by the routine. When you use the interrupt keyword with the definition of the function, the compiler generates register saves based on the rules for interrupt functions and the special return sequence for interrupts.

You can use the interrupt keyword with a function that is defined to return void and that has no parameters. The body of the interrupt function can have local variables and is free to use the stack. For example:

```c
interrupt void int_handler()
{
    unsigned int flags;
    ...
}
```

The name c_int00 is the C/C++ entry point. This name is reserved for the system reset interrupt. This special interrupt routine initializes the system and calls the function main. Because it has no caller, c_int00 does not save any registers.

Use the alternate keyword, \_\_interrupt, if you are writing code for strict ISO mode (using the \-ps shell option).

5.4.4 The onchip Keyword

The onchip (or \_\_onchip) keyword informs the compiler that a pointer points to data that may be used as an operand to a dual MAC instruction. Data passed to a function with onchip parameters, or data that will be eventually referenced through an onchip expression, must be linked into on-chip memory (not external memory). Failure to link the data appropriately can result in a reference to external memory through the BB data bus, which will generate a bus error.

```c
onchip int x[100]; /* array declaration */
onchip int *p; /* pointer declaration */
```

The \-mb shell option specifies that all data memory will be on-chip.
5.4.5 The restrict Keyword

To help the compiler determine memory dependencies, you can qualify a pointer, reference, or array with the restrict keyword. The restrict keyword is a type qualifier that may be applied to pointers, references, and arrays. Its use represents a guarantee by the programmer that within the scope of the pointer declaration the object pointed to can be accessed only by that pointer. Any violation of this guarantee renders the program undefined. This practice helps the compiler optimize certain sections of code because aliasing information can be more easily determined.

In Example 5–4, the restrict keyword is used to tell the compiler that the function func1 is never called with the pointers a and b pointing to objects that overlap in memory. The user is promising that accesses through a and b never conflict; this means that a write through one pointer cannot affect a read from any other. The precise semantics of the restrict keyword are described in the 1999 version of the ISO C standard.

Example 5–4. Use of the restrict Type Qualifier With Pointers

```c
void func1(int * restrict a, int * restrict b)
{
    int i
    for(i=0; i<64; i++) *a++=*b++;
}
```

Example 5–5 illustrates using the restrict keyword when passing arrays to a function. Here, the arrays c and d should not overlap, nor should c and d point to the same array.

Example 5–5. Use of the restrict Type Qualifier With Arrays

```c
void func2(int c[restrict], int d[restrict])
{
    int i;
    for(i = 0; i < 64; i++)
    {
        c[i] += d[i];
        d[i] += 1;
    }
}
5.4.6 The volatile Keyword

The optimizer analyzes data flow to avoid memory accesses whenever possible. If you have code that depends on memory accesses exactly as written in the C/C++ code, you must use the volatile keyword to identify these accesses. The compiler won’t optimize out any references to volatile variables.

In the following example, the loop waits for a location to be read as 0xFF:

```c
unsigned int *ctrl;
while (*ctrl != 0xFF);
```

In this example, *ctrl is a loop-invariant expression, so the loop is optimized down to a single-memory read. To correct this, declare ctrl as:

```c
volatile unsigned int *ctrl;
```
5.5 Register Variables and Parameters

The C/C++ compiler treats register variables (variables declared with the register keyword) differently, depending on whether you use the optimizer.

- **Compiling with the optimizer**
  
The compiler ignores any register declarations and allocates registers to variables and temporary values by using a cost algorithm that attempts to make the most efficient use of registers.

- **Compiling without the optimizer**
  
  If you use the register keyword, you can suggest variables as candidates for allocation into registers. The same set of registers used for allocation of temporary expression results is used for allocation of register variables.

  The compiler attempts to honor all register definitions. If the compiler runs out of appropriate registers, it frees a register by moving its contents to memory. If you define too many objects as register variables, you limit the number of registers the compiler has for temporary expression results. The limit causes excessive movement of register contents to memory.

  Any object with a scalar type (integer, floating point, or pointer) can be declared as a register variable. The register designator is ignored for objects of other types.

  The register storage class is meaningful for parameters as well as local variables. Normally, in a function, some of the parameters are copied to a location on the stack where they are referenced during the function body. A register parameter is copied to a register instead of the stack. This action speeds access to the parameter within the function.

  For more information on register variables, see section 6.3, *Register Conventions*, on page 6-12.
5.6 The asm Statement

The TMS320C55x C/C++ compiler can embed C55x assembly language instructions or directives directly into the assembly language output of the compiler. This capability is an extension to the C/C++ language—the *asm* statement. The *asm* (or *__asm*) statement provides access to hardware features that C/C++ cannot provide. The *asm* statement is syntactically like a call to a function named *asm*, with one string-constant argument:

```
asm("assembler text");
```

The compiler copies the argument string directly into your output file. The assembler text must be enclosed in double quotes. All the usual character string escape codes retain their definitions. For example, you can insert a .string directive that contains quotes as follows:

```
asm("STR: .string \"abc\"");
```

The inserted code must be a legal assembly language statement. Like all assembly language statements, the line of code inside the quotes must begin with a label, a blank, a tab, or a comment (asterisk or semicolon). The compiler performs no checking on the string; if there is an error, the assembler detects it. For more information about assembly language statements, see the *TMS320C55x Assembly Language Tools User’s Guide*.

The *asm* statements do not follow the syntactic restrictions of normal C/C++ statements. Each can appear as a statement or a declaration, even outside of blocks. This is useful for inserting directives at the very beginning of a compiled module.

**Note:** Avoid Disrupting the C/C++ Environment With *asm* Statements

Be careful not to disrupt the C/C++ environment with *asm* statements. The compiler does not check the inserted instructions. Inserting jumps and labels into C/C++ code can cause unpredictable results in variables manipulated in or around the inserted code. Directives that change sections or otherwise affect the assembly environment can also be troublesome.

Be especially careful when you use the optimizer with *asm* statements. Although the optimizer cannot remove *asm* statements, it can significantly rearrange the code order near them, possibly causing undesired results.
5.7 Pragma Directives

Pragma directives tell the compiler’s preprocessor how to treat functions. The C55x C/C++ compiler supports the following pragmas:

- CODE_SECTION
- C54X_CALL
- C54X_FAR_CALL
- DATA_ALIGN
- DATA_SECTION
- FAR – only used for extaddr.h
- FUNC_CANNOT_INLINE
- FUNC_EXT_CALLED
- FUNC_ISPURE
- FUNC_IS_SYSTEM
- FUNC_NEVER_RETURNS
- FUNC_NO_GLOBAL_ASG
- FUNC_NO_IND_ASG
- INTERRUPT
- MUST_ITERATE
- UNROLL

The arguments func and symbol cannot be defined or declared inside the body of a function. You must specify the pragma outside the body of a function, and it must occur before any declaration, definition, or reference to the func or symbol argument. If you do not follow these rules, the compiler issues a warning.

For pragmas that apply to functions or symbols, the syntax for the pragmas differs between C and C++. In C, you must supply, as the first argument, the name of the object or function to which you are applying the pragma. In C++, the name is omitted; the pragma applies to the declaration of the object or function that follows it.

When you mark a function with a pragma, you assert to the compiler that the function meets the pragma’s specifications in every circumstance. If the function does not meet these specifications at all times, the compiler’s behavior will be unpredictable.
5.7.1 The CODE_SECTION Pragma

The CODE_SECTION pragma allocates space for the symbol in a section named section name.

The syntax of the pragma in C is:

```
#pragma CODE_SECTION (symbol, "section name") [i]
```

The syntax of the pragma in C++ is:

```
#pragma CODE_SECTION ("section name") [i]
```

The CODE_SECTION pragma is useful if you have code objects that you want to link into an area separate from the .text section.

Example 5–6 demonstrates the use of the CODE_SECTION pragma.

**Example 5–6. Using the CODE_SECTION Pragma**

(a) C source file

```
#pragma CODE_SECTION(funcA,"codeA")
int funcA(int a)
{
    int i;
    return (i = a);
}
```

(b) Assembly source file

```
.sect "codeA"
.global _funcA

;***************************
;* FUNCTION NAME: _funcA *
;***************************
_funcA:
    RET
```
Example 5–6. Using the CODE_SECTION Pragma (Continued)

(c) C++ source file

```c
#pragma CODE_SECTION("codeB")
int i_arg(int x) { return 1; }
int f_arg(float x) { return 2; }
```

(d) Assembly source file

```asm
.sect "codeB"
_i_arg__Fi:
    MOV #1, T0
    RET
.sect ".text"
_f_arg__Ff:
    MOV #2, T0
    RET
```

5.7.2 The C54X_CALL and C54X_FAR_CALL Pragmas

The C54X_CALL and C54X_FAR_CALL pragmas provide a method for making calls from C55x C code to C54x assembly functions ported with masm55. These pragmas handle the differences in the C54x and C55x run-time environments.

The syntax for these pragmas in C is:

```c
#pragma C54X_CALL (asm_function) []
```

```c
#pragma C54X_FAR_CALL (asm_function) []
```

The syntax for these pragmas in C++ is:

```c
#pragma C54X_CALL
```

```c
#pragma C54X_FAR_CALL
```

The `function` is a C54x assembly function, unmodified for C55x in any way, that is known to work with the C54x C compiler. This pragma cannot be applied to a C function.

The appropriate pragma must appear before any declaration or call to the assembly function. Consequently, it should most likely be specified in a header file.
Use C54X_FAR_CALL only when calling C54x assembly functions that must be called with FCALL.

Use C54X_CALL for any other call to a C54x assembly function. This includes calls that use the __far_mode symbol to decide at assembly time whether to use either CALL or FCALL. Such calls always use CALL on C55x.

When the compiler encounters one of these pragmas, it will:

1) Temporarily adopt the C54x calling conventions and the run-time environment required for ported C54x assembly code. For more information on the C54x run-time environment, see the TMS320C54x Optimizing C Compiler User’s Guide.

2) Call the specified assembly function.

3) Capture the result.

4) Revert to the native C55x calling conventions and run-time environment.

These pragmas do not provide support for C54x assembly functions that call C code. In this case, you must modify the assembly code to account for the differences in the C54x and C55x run-time environments. For more information, see the Migrating a C54x System to a C55x System chapter in the TMS320C55x Assembly Language Tools User’s Guide.

C54x assembly code ported for execution on C55x requires the use of 32-bit stack mode. However, the reset vector in the C55x run-time library (in vectors.asm) sets the stack to be in fast return mode. If you use the C54X_CALL or C54X_FAR_CALL pragma in your code, you must change the reset vector as follows:

1) Extract vectors.asm from rts.src. The rts.src file is located in the lib subdirectory.

   ar55 -x rts.src vectors.asm

2) In vectors.asm, change the following line:

   _Reset:  .ivec _c_int00, USE_RETA

to be:

   _Reset:  .ivec _c_int00, C54X_STK

3) Re-assemble vectors.asm:

   asm55 vectors.asm

4) Place the new file into the object and source libraries.

   ar55 -r rts55.lib vectors.obj
   ar55 -r rts55x.lib vectors.obj
   ar55 -r rts.src vectors.asm
Note: Modifying the Run-Time Libraries Installed With Code Composer Studio

To modify the source and object libraries installed with Code Composer Studio, you must turn off the Read-only attribute for the files. Select the appropriate run-time library file in Windows Explorer, open its Properties dialog, and remove the check from the Read-only checkbox.

These pragmas cannot be used in:

- Indirect calls.
- Files compiled for the C55x large memory model (with the −ml shell option). Data pointers in the large memory model are 23 bits. When passed on the stack, the pointers occupy two words, which is incompatible with functions that expect these pointers to occupy one word.

Note that the C55x C compiler does not support the global register capability of the C54x C compiler.

5.7.3 The DATA_ALIGN Pragma

The DATA_ALIGN pragma aligns the symbol to an alignment boundary. The boundary is the value of the constant in words. For example, a constant of 4 specifies a 64-bit alignment. The constant must be a power of 2.

The syntax of the pragma in C is:

```c
#pragma DATA_ALIGN (symbol, constant) []
```

The syntax of the pragma in C++ is:

```cpp
#pragma DATA_ALIGN (constant) []
```
5.7.4 The DATA_SECTION Pragma

The DATA_SECTION pragma allocates space for the symbol in a section named section name. This is useful if you have data objects that you want to link into an area separate from the .bss section.

The syntax for the pragma in C is:

```
#pragma DATA_SECTION (symbol, "section name") [;
```

The syntax for the pragma in C++ is:

```
#pragma DATA_SECTION ("section name") [;
```

Example 5–7 demonstrates the use of the DATA_SECTION pragma.

**Example 5–7. Using the DATA_SECTION Pragma**

(a) C source file

```
#pragma DATA_SECTION(bufferB, "my_sect")
char bufferA[512];
char bufferB[512];
```

(b) C++ source file

```
char bufferA[512];
#pragma DATA_SECTION("my_sect")
char bufferB[512];
```

(c) Assembly source file

```
.global _bufferA
.bufferA: .bss bufferA,512,0,0
.global _bufferB
.bufferB: .usect "my_sect",512,0,0
```
5.7.5 The FAR Pragma

The pragma FAR may be used to obtain the full 23-bit address of a data object declared at file scope. The pragma is used only for the extaddr.h header file and is only available in P2 Reserved Mode.

The syntax of the pragma in C is:

```
#pragma FAR (x);
```

The syntax of the pragma in C++ is:

```
#pragma FAR;
```

The pragma must immediately precede the definition of the symbol to which it applies as shown in Example 5−8.

This pragma may ONLY be applied to objects declared at file scope. Once this is done, taking the address of the indicated object produces the 23-bit value that is the full address of the object. This value may be cast to FARPTR (that is, unsigned long) and passed to the runtime support functions. For a structured object, taking the address of a field also produces a full address.

Example 5–8. Using the FAR Pragma

```
#pragma FAR(x)
int x; /* ok */

#pragma FAR(z)
int y; /* error - z’s definition must */
int z; /* immediately follow #pragma */
```
5.7.6 The FUNC_CANNOT_INLINE Pragma

The FUNC_CANNOT_INLINE pragma instructs the compiler that the named function cannot be expanded inline. Any function named with this pragma overrides any inlining designated in any other way, such as by using the inline keyword.

The pragma must appear before any declaration or reference to the function.

The syntax of the pragma in C is:

```
#pragma FUNC_CANNOT_INLINE (func) ;
```

The syntax for the pragma in C++ is:

```
#pragma FUNC_CANNOT_INLINE ;
```

In C, the argument `func` is the name of the function that cannot be inlined. In C++, the pragma applies to the next function declared. For more information, see section 2.9, *Using Inline Function Expansion*, on page 2-45.

5.7.7 The FUNC_EXT_CALLED Pragma

When you use the −pm option, the compiler uses program-level optimization. When you use this type of optimization, the compiler removes any function that is not called, directly or indirectly, by main. You might have C/C++ functions that are called by hand-coded assembly instead of main.

The FUNC_EXT_CALLED pragma specifies to the optimizer to keep these C/C++ functions or any other functions called by these C/C++ functions. These functions act as entry points into C/C++.

The pragma must appear before any declaration or reference to the function.

The syntax of the pragma in C is:

```
#pragma FUNC_EXT_CALLED (func) ;
```

The syntax of the pragma in C++ is:

```
#pragma FUNC_EXT_CALLED ;
```

In C, the argument `func` is the name of the function that you do not want to be removed. In C++, the pragma applies to the next function declared.
Except for _c_int00, which is the name reserved for the system reset interrupt for C/C++ programs, the name of the func argument does not need to conform to a naming convention.

When you use program-level optimization, you may need to use the FUNC_EXT_CALLED pragma with certain options. For more information, see section 3.3.2, *Optimization Considerations When Using Mixing C and Assembly*, on page 3-7.

### 5.7.8 The FUNC_IS_PURE Pragma

The FUNC_IS_PURE pragma specifies to the optimizer that the named function has no side effects. This allows the optimizer to do the following:

- Delete the call to the function if the function’s value is not needed
- Delete duplicate functions

The pragma must appear before any declaration or reference to the function.

If you use this pragma on a function that does have side effects, the optimizer could delete these side effects.

The syntax of the pragma in C is:

```
#pragma FUNC_IS_PURE (func) ;
```

In C, the argument *func* is the name of a function. In C++, the pragma applies to the next function declared.
5.7.9 The FUNC_IS_SYSTEM Pragma

The FUNC_IS_SYSTEM pragma specifies to the optimizer that the named function has the behavior defined by the ISO standard for a function with that name.

This pragma can only be used with a function described in the ISO standard (such as strcmp or memcpy). It allows the compiler to assume that you haven’t modified the ISO implementation of the function. The compiler can then make assumptions about the implementation. For example, it can make assumptions about the registers used by the function.

Do not use this pragma with an ISO function that you have modified.

The pragma must appear before any declaration or reference to the function.

The syntax of the pragma in C is:

```
#pragma FUNC_IS_SYSTEM (func) []
```

In C, the argument `func` is the name of the function to treat as an ISO standard function. In C++, the pragma applies to the next function declared.

5.7.10 The FUNC_NEVER_RETURNS Pragma

The FUNC_NEVER_RETURNS pragma specifies to the optimizer that, in all circumstances, the function never returns to its caller. For example, a function that loops infinitely, calls exit(), or halts the processor will never return to its caller. When a function is marked by this pragma, the compiler will not generate a function epilog (to unwind the stack, etc.) for the function.

The pragma must appear before any declaration or reference to the function.

The syntax of the pragma in C is:

```
#pragma FUNC_NEVER_RETURNS (func) []
```

In C, the argument `func` is the name of the function that does not return. In C++, the pragma applies to the next function declared.
5.7.11 The FUNC_NO_GLOBAL_ASG Pragma

The FUNC_NO_GLOBAL_ASG pragma specifies to the optimizer that the function makes no assignments to named global variables and contains no asm statements.

The pragma must appear before any declaration or reference to the function.

The syntax of the pragma in C is:

```c
#pragma FUNC_NO_GLOBAL_ASG (func) ;
```

In C, the argument `func` is the name of the function that makes no assignments.

5.7.12 The FUNC_NO_IND_ASG Pragma

The FUNC_NO_IND_ASG pragma specifies to the optimizer that the function makes no assignments through pointers and contains no asm statements.

The pragma must appear before any declaration or reference to the function.

The syntax of the pragma in C is:

```c
#pragma FUNC_NO_IND_ASG (func) ;
```

In C, the argument `func` is the name of the function that makes no assignments.
5.7.13 The INTERRUPT Pragma

The INTERRUPT pragma enables you to handle interrupts directly with C code. In C, the argument `func` is the name of a function. In C++, the pragma applies to the next function declared.

The syntax of the pragma in C is:

```
#pragma INTERRUPT (func) []
```

The syntax of the pragma in C++ is:

```
#pragma INTERRUPT []
```

The code for the function will return via the IRP (interrupt return pointer).

Except for `_c_int00`, which is the name reserved for the system reset interrupt for C programs, the name of the interrupt (the `func` argument) does not need to conform to a naming convention.

5.7.14 The MUST_ITERATE Pragma

The MUST_ITERATE pragma specifies to the compiler certain properties of a loop. Through the use of the MUST_ITERATE pragma, you can guarantee that a loop executes a certain number of times. The information provided by this pragma helps the compiler to determine if it can generate a hardware loop (localrepeat or blockrepeat) for the loop. The pragma can also help the compiler eliminate unnecessary code.

In general, the compiler cannot use a hardware loop (localrepeat or blockrepeat) if a loop’s bounds are too complicated. However, if you specify MUST_ITERATE with the exact number of the loop’s iterations, the compiler may be able to use a hardware loop to increase performance and reduce code size.

This pragma is also useful if you know the minimum number of a loop’s iterations. When you specify the minimum number via MUST_ITERATE, the compiler may be able to eliminate code that, in the event of 0 iterations, bypasses the hardware loop. For detailed information, see section 5.7.14.1, *Using the MUST_ITERATE Pragma to Expand Compiler Knowledge of Loops*, on page 5-29.

Any time the UNROLL pragma is applied to a loop, MUST_ITERATE should be applied to the same loop. In this case, the MUST_ITERATE pragma’s third argument, `multiple`, should always be specified.
No statements are allowed between the MUST_ITERATE pragma and the for, while, or do-while loop to which it applies. However, other pragmas, such as UNROLL, can appear between the MUST_ITERATE pragma and the loop.

The syntax of the pragma for C and C++ is:

```
#pragma MUST_ITERATE (min, max, multiple) ;
```

The arguments min and max are programmer-guaranteed minimum and maximum trip counts. The trip count is the number of times a loop iterates. The trip count of the loop must be evenly divisible by multiple. All arguments are optional. For example, if the trip count could be 5 or greater, you can specify the argument list as follows:

```
#pragma MUST_ITERATE(5);
```

However, if the trip count could be any nonzero multiple of 5, the pragma would look like this:

```
#pragma MUST_ITERATE(5, , 5); /* A blank field for max*/
```

It is sometimes necessary for you to provide min and multiple in order for the compiler to perform unrolling. This is especially the case when the compiler cannot easily determine how many iterations the loop will perform (i.e., the loop has a complex exit condition).

When specifying a multiple via the MUST_ITERATE pragma, results of the program are undefined if the trip count is not evenly divisible by multiple. Also, results of the program are undefined if the trip count is less than the minimum or greater than the maximum specified.

If no min is specified, zero is used. If no max is specified, the largest possible number is used. If multiple MUST_ITERATE pragmas are specified for the same loop, the smallest max and largest min are used.

### 5.7.14.1 Using MUST_ITERATE to Expand Compiler Knowledge of Loops

Through the use of the MUST_ITERATE pragma, you can guarantee that a loop executes a certain number of times. The example below tells the compiler that the loop is guaranteed to run exactly 10 times:

```
#pragma MUST_ITERATE(10,10);
for(i = 0; i < trip_count; i++) { ...}
```

In this example, if trip_count is a 16-bit variable, the compiler will generate a hardware loop even without the pragma. However, if MUST_ITERATE is not specified for a loop such as this, the compiler generates code to bypass the loop, to account for the possibility of 0 iterations. With the pragma specification, the compiler knows that the loop iterates at least once and can eliminate the loop-bypassing code.
When trip_count is a 32-bit variable, the compiler can’t automatically generate a hardware loop. In this case, consider using MUST_ITERATE to specify the upper bound on the iteration count. If the upper bound is a 16-bit value (to fit in the BRC0, BRC1, or CSR register), the compiler can generate a hardware loop.

MUST_ITERATE can specify a range for the trip count as well as a factor of the trip count. For example:

```c
#pragma MUST_ITERATE(8, 48, 8);
for(i = 0; i < trip_count; i++) { ...}
```

This example tells the compiler that the loop executes between 8 and 48 times and that the trip_count variable is a multiple of 8 (8, 16, 24, 32, 40, 48). The multiple argument allows the compiler to unroll the loop.

You should also consider using MUST_ITERATE for loops with complicated bounds. In the following example:

```c
for(i2 = ipos[2]; i2 < 40; i2 += 5) { ...}
```

the compiler would have to generate a divide function call to determine, at run time, the exact number of iterations performed. The compiler will not do this. In this case, using MUST_ITERATE to specify that the loop always executes 8 times allows the compiler to generate a hardware loop:

```c
#pragma MUST_ITERATE(8, 8);
for(i2 = ipos[2]; i2 < 40; i2 += 5) { ...}
```

5.7.15 The UNROLL Pragma

The UNROLL pragma specifies to the compiler how many times a loop should be unrolled. The optimizer must be invoked (use −O1, −O2, or −O3) in order for pragma-specified loop unrolling to take place. The compiler has the option of ignoring this pragma.

No statements are allowed between the UNROLL pragma and the for, while, or do-while loop to which it applies. However, other pragmas, such as MUST_ITERATE, can appear between the UNROLL pragma and the loop.

The syntax of the pragma for C and C++ is:

```c
#pragma UNROLL (n) [,]
```

If possible, the compiler unrolls the loop so there are $n$ copies of the original loop. The compiler only unrolls if it can determine that unrolling by a factor of $n$ is safe. In order to increase the chances the loop is unrolled, the compiler needs to know certain properties:

- The loop iterates a multiple of $n$ times. This information can be specified to the compiler via the multiple argument in the MUST_ITERATE pragma.
The smallest possible number of iterations of the loop.

The largest possible number of iterations of the loop.

The compiler can sometimes obtain this information itself by analyzing the code. However, the compiler can be overly conservative in its assumptions and may generate more code than is necessary when unrolling. This can also lead to not unrolling at all.

Furthermore, if the mechanism that determines when the loop should exit is complex, the compiler may not be able to determine these properties of the loop. In these cases, you must tell the compiler the properties of the loop by using the MUST_ITERATE pragma.

The following pragma specification:

```c
#pragma UNROLL(1);
```

asks that the loop not be unrolled. Automatic loop unrolling also is not performed in this case.

If multiple UNROLL pragmas are specified for the same loop, it is undefined which UNROLL pragma is used, if any.
5.8 Generating Linknames

The compiler transforms the names of externally visible identifiers when creating their linknames. The algorithm used depends on the scope within which the identifier is declared. For objects and C functions, an underscore (_) is prefixed to the identifier name. C++ functions are prefixed with an underscore also, but the function name is modified further.

Mangling is the process of embedding a function’s signature (the number and type of its parameters) into its name. Mangling occurs only in C++ code. The mangling algorithm used closely follows that described in *The Annotated Reference Manual* (ARM). Mangling allows function overloading, operator overloading, and type-safe linking.

For example, the general form of a C++ linkname for a function named func is:

\[ \_\_func\_F\text{parmcodes} \]

where *parmcodes* is a sequence of letters that encodes the parameter types of func.

For this simple C++ source file:

```cpp
int foo(int i); //global C++ function
```

the resulting assembly code is:

\[ \_\_foo\_Fi; \]

The linkname of foo is \_\_foo\_Fi, indicating that foo is a function that takes a single argument of type int. To aid inspection and debugging, a name demangling utility is provided that demangles names into those found in the original C++ source. See Chapter 9, *C++ Name Demangling*, for more information.
5.9 Initializing Static and Global Variables

The ISO C standard specifies that static and global (extern) variables without explicit initializations must be initialized to 0 before the program begins running. This task is typically performed when the program is loaded. Because the loading process is heavily dependent on the specific environment of the target application system, the compiler itself makes no provision for preinitializing variables at run time. It is up to your application to fulfill this requirement.

5.9.1 Initializing Static and Global Variables With the Linker

If your loader does not preinitialize variables, you can use the linker to preinitialize the variables to 0 in the object file. For example, in the linker command file, use a fill value of 0 in the .bss section:

```
SECTIONS
{
   ...
   .bss: fill = 0x00;
   ...
}
```

Because the linker writes a complete load image of the zeroed .bss section into the output COFF file, this method can have the unwanted effect of significantly increasing the size of the output file (but not the program).

If you burn your application into ROM, you should explicitly initialize variables that require initialization. The method demonstrated above initializes .bss to 0 only at load time, not at system reset or power up. To make these variables 0 at run time, explicitly define them in your code.

For more information about linker command files and the SECTIONS directive, see the linker description information in the TMS320C55x Assembly Language Tools User’s Guide.
5.9.2 Initializing Static and Global Variables With the Const Type Qualifier

Static and global variables of type `const` without explicit initializations are similar to other static and global variables because they might not be preinitialized to 0 (for the same reasons discussed in section 5.9, Initializing Static and Global Variables). For example:

```c
const int zero; /* may not be initialized to 0 */
```

However, the initialization of `const` global and static variables is different because these variables are declared and initialized in a section called `.const`. For example:

```c
const int zero = 0 /* guaranteed to be 0 */
```

corresponds to an entry in the `.const` section:

```
.sect .const
_zero
.word 0
```

The feature is particularly useful for declaring a large table of constants, because neither time nor space is wasted at system startup to initialize the table. Additionally, the linker can be used to place the `.const` section in ROM.

You can use the `DATA_SECTION` pragma to put the variable in a section other than `.const`. For example, the following C code:

```c
#pragma DATA_SECTION (var, ".mysect");
const int zero=0;
```

is compiled into this assembly code:

```
.sect .mysect
_zero
.word 0
```
5.10 Changing the ISO C Language Mode (−pk, −pr, and −ps Options)

The −pk, −pr, and −ps options let you specify how the C/C++ compiler interprets your source code. You can compile your source code in the following modes:

- Normal ISO mode
- K&R C mode
- Relaxed ISO mode
- Strict ISO mode

The default is normal ISO mode. Under normal ISO mode, most ISO violations are emitted as errors. Strict ISO violations (those idioms and allowances commonly accepted by C/C++ compilers, although violations with a strict interpretation of ISO), however, are emitted as warnings. Language extensions, even those that conflict with ISO C, are enabled.

K&R C mode does not apply to C++ code.

5.10.1 Compatibility With K&R C (−pk Option)

The ISO C language is basically a superset of the C dialect defined in Kernighan and Ritchie’s *The C Programming Language*. Most programs written for other non-ISO compilers correctly compile and run without modification.

There are subtle changes, however, in the language that can affect existing code. Appendix C in *The C Programming Language* (second edition, referred to in this manual as K&R) summarizes the differences between ISO C and the first edition’s previous C standard (the first edition is referred to in this manual as K&R C).

To simplify the process of compiling existing C programs with the C55x ISO C/C++ compiler, the compiler has a K&R option (−pk) that modifies some semantic rules of the language for compatibility with older code. In general, the −pk option relaxes requirements that are stricter for ISO C than for K&R C. The −pk option does not disable any new features of the language such as function prototypes, enumerations, initializations, or preprocessor constructs. Instead, −pk simply liberalizes the ISO rules without revoking any of the features.
The specific differences between the ISO version of C and the K&R version of C are as follows:

- The integral promotion rules have changed regarding promoting an unsigned type to a wider signed type. Under K&R C, the result type was an unsigned version of the wider type; under ISO, the result type is a signed version of the wider type. This affects operations that perform differently when applied to signed or unsigned operands; namely, comparisons, division (and mod), and right shift:

```c
unsigned short u;
int i;
if (u < i) ... /* SIGNED comparison, unless -pk used */
```

- ISO prohibits combining two pointers to different types in an operation. In most K&R compilers, this situation produces only a warning. Such cases are still diagnosed when -pk is used, but with less severity:

```c
int *p;
char *q = p; /* error without -pk, warning with -pk */
```

- External declarations with no type or storage class (only an identifier) are illegal in ISO but legal in K&R:

```c
a;    /* illegal unless -pk used */
```

- ISO interprets file scope definitions that have no initializers as tentative definitions: in a single module, multiple definitions of this form are fused together into a single definition. Under K&R, each definition is treated as a separate definition, resulting in multiple definitions of the same object and usually an error. For example:

```c
int a;
int a;    /* illegal if -pk used, OK if not */
```

Under ISO, the result of these two definitions is a single definition for the object a. For most K&R compilers, this sequence is illegal, because `int a` is defined twice.

- ISO prohibits, but K&R allows, objects with external linkage to be redeclared as static:

```c
extern int a;
static int a;    /* illegal unless -pk used */
```

- Unrecognized escape sequences in string and character constants are explicitly illegal under ISO but ignored under K&R:

```c
char c = '\q';    /* same as 'q' if -pk used, error if not */
```
Changing the ISO C Language Mode (−pk, −pr, and –ps Options)

- ISO specifies that bit fields must be of type int or unsigned. With −pk, bit fields can be legally declared with any integral type. For example:

```c
struct s
{
    short f : 2; /* illegal unless −pk used */
};
```

- K&R syntax allows a trailing comma in enumerator lists:

```c
enum { a, b, c, }; /* illegal unless −pk used */
```

- K&R syntax allows trailing tokens on preprocessor directives:

```
#define NAME /* illegal unless −pk used */
```

5.10.2 Enabling Strict ISO Mode and Relaxed ISO Mode (−ps and –pr Options)

Use the −ps option when you want to compile under strict ISO mode. In this mode, error messages are provided when non-ISO features are used, and language extensions that could invalidate a strictly conforming program are disabled. Examples of such extensions are the inline and asm keywords.

Use the –pr option when you want the compiler to ignore strict ISO violations rather than emit a warning (as occurs in normal ISO mode) or an error message (as occurs in strict ISO mode). In relaxed ISO mode, the compiler accepts extensions to the ISO C standard, even when they conflict with ISO standard C.

5.10.3 Enabling Embedded C++ Mode (−pe Option)

The compiler supports the compilation of embedded C++. In this mode, some features of C++ are removed that are of less value or too expensive to support in an embedded system. Embedded C++ omits these C++ features:

- Templates
- Exception handling
- Run-time type information
- The new cast syntax
- The keyword /mutable/
- Multiple inheritance
- Virtual inheritance

In the standard definition of embedded C++, namespaces and using-declarations are not supported. The C55x compiler nevertheless allows these features under embedded C++ because the C++ run-time support library makes use of them. Furthermore, these features impose no run-time penalty.
Due to the variety of host systems supported by the C55x C/C++ compiler and the limitations of some of these systems, the compiler may not be able to successfully compile source files that are excessively large or complex. In general, exceeding such a system limit prevents continued compilation, so the compiler aborts immediately after printing the error message. Simplify the program to avoid exceeding a system limit.

Some systems do not allow filenames longer than 500 characters. Make sure your filenames are shorter than 500.

The compiler has no arbitrary limits but is limited by the amount of memory available on the host system. On smaller host systems such as PCs, the optimizer may run out of memory. If this occurs, the optimizer terminates and the shell continues compiling the file with the code generator. This results in a file compiled with no optimization. The optimizer compiles one function at a time, so the most likely cause of this is a large or extremely complex function in your source module. To correct the problem, your options are:

- Don’t optimize the module in question.
- Identify the function that caused the problem and break it down into smaller functions.
- Extract the function from the module and place it in a separate module that can be compiled without optimization so that the remaining functions can be optimized.
Chapter 6

Run-Time Environment

This chapter describes the TMS320C55x™ C/C++ run-time environment. To ensure successful execution of C/C++ programs, it is critical that all run-time code maintain this environment. It is also important to follow the guidelines in this chapter if you write assembly language functions that interface with C/C++ code.

6.1 Memory

The C55x compiler treats memory as a single linear block that is partitioned into sub-blocks of code and data. Each sub-block of code or data generated by a C program is placed in its own continuous memory space. The compiler assumes that a full 24-bit address space is available in target memory.

**Note: The Linker Defines the Memory Map**

The linker, not the compiler, defines the memory map and allocates code and data into target memory. The compiler assumes nothing about the types of memory available, about any locations not available for code or data (holes), or about any locations reserved for I/O or control purposes. The compiler produces relocatable code that allows the linker to allocate code and data into the appropriate memory spaces.

For example, you can use the linker to allocate global variables into fast internal RAM or to allocate executable code into external ROM. You can allocate each block of code or data individually into memory, but this is not a general practice (an exception to this is memory-mapped I/O, although you can access physical memory locations with C/C++ pointer types).

The compiler supports a small memory model and a large memory model. These memory models affect how data is placed in memory and accessed.

### 6.1.1 Small Memory Model

The use of the small memory model results in code and data sizes that are slightly smaller than when using the large memory model. However, your program must meet certain size and memory placement restrictions.

In the small memory model, the following sections must all fit within a single page of memory that is 64K words in size.

- The .bss and .data sections (all static and global data)
- The .stack and .sysstack sections (the primary and secondary system stacks)
- The .sysmem section (dynamic memory space)
- The .const section

There is no restriction on the size or placement of .text sections (code), .switch sections (switch statements), or .cinit/.pinit sections (variable initialization).

In the small model, the compiler uses 16-bit data pointers to access data. The upper 7 bits of the XARn registers are set to point to the page that contains the .bss section. They remain set to that value throughout program execution.
6.1.2 Large Memory Model

The large memory model supports an unrestricted placement of data. To use the large memory model, use the −ml shell option.

In the large model:

- Data pointers are 23 bits and occupy two words when stored in memory.
- The .stack and .sysstack sections must be on the same page.

**Note: Placement of Data**

Only code sections are allowed to cross page boundaries. Any other type of section must fit on one page.

When you compile code for the large memory model, you must link with the rts55x.lib run-time library. Note that you must use the same memory model for all of the files in your application. The linker will not accept a mix of large memory model and small memory model code.

In the small model, code will also initialize all 7-bit MDPxx registers to 0, ensuring that all data accesses are in Page 0.

6.1.3 Huge Memory Model

In the huge model, objects can be as large as desired, up to the 8MB limit of memory space. To take advantage of the huge memory model, you need to recompile your C source files, re-assemble your hand-coded assembly files, and use the library rts55h.lib for standard library functions. In both C and assembly code, you can use the predefined macro __HUGE_MODEL__ to conditionally compile code depending on the model. However, you should not need to use __HUGE_MODEL__ in C code with the proper use of the size_t and ptrdiff_t types.

In the huge model, size_t and ptrdiff_t are both 32-bit types. The change in size affects structures containing members of these types and functions that have these types as parameters or return value types (notably memcpy, sizeof, and malloc). If you rely on the binary image of the run-time-support libraries (such as for sharing structures with a co-processor), this change to structures and function may impact your code.

The performance of huge model is similar to that of large model; however, there is one case of inefficiency you might notice. Since the C55x zero-overhead looping construct (RPT, RPTB) allows only a 16-bit loop count, loops that iterate over size_t values will now be done with the less efficient conditional branch. However, calls to the library string functions that can be inlined (e.g. memcpy) with a constant count less than 16 bits will still be done with RPT.
Since `ptrdiff_t` is now a 32-bit value, pointer comparisons must be done in the D–unit accumulators. This code will be slower and slightly larger than the former A–unit comparison which can still be done in small model. This is an unavoidable cost of large and huge models.

Object files generated in the huge model are incompatible with both the large and small models, and also incompatible with CPU revisions earlier than 3.0. The compiler and linker will enforce using CPU revision 3.0 for huge model, and will prevent linking small and large model objects.

The compiler and linker will prevent object files optimized for CPU revisions 1 and 2 only from being combined with object files optimized for CPU revision 3 only. The default is not to optimize for any particular CPU revision, which will generate a maximally-compatible object file. However, object files generated with older versions of the tools will not be checked for CPU revision compatibility.

The linker will prevent objects in the standard compiler-generated sections (see section 6.1.4) from crossing page boundaries in the small memory model and for code which can execute on CPU revisions 1 and 2. You will get an error naming the section that attempts to cross a page boundary.

---

**Note: Missing Features of Huge Memory Model**

The dynamic memory allocation system has not yet been updated to take advantage of the more flexible object size; this will be addressed in a future release of the tools.

Global object initializers do not work for objects of $2^{14}$ characters or larger. This is a limitation of the initialization scheme, and a fix is being developed.

The compiler does not issue a warning when you declare an object larger than allowed in the selected memory model.

---

### 6.1.4 Sections

The compiler produces relocatable blocks of code and data. These blocks are called *sections*. These sections are allocated into memory in a variety of ways to conform to a variety of system configurations. For more information about COFF sections, see the *Introduction to Common Object File Format* chapter in the *TMS320C55x Assembly Language Tools User’s Guide*. 
There are two basic types of sections:

- **Initialized sections** contain data or executable code. The C/C++ compiler creates the following initialized sections:
  - The **.cinit section** contains tables for initializing variables and constants.
  - The **.pinit section** contains the table for calling global object constructors at run time.
  - The **.const section** contains string constants and data defined with the C/C++ qualifier `const` (provided the constant is not also defined as `volatile`).
  - The **.switch section** contains tables for switch statements.
  - The **.text section** contains all the executable code.

- **Uninitialized sections** reserve space in memory (usually RAM). A program can use this space at run time for creating and storing variables. The compiler creates the following uninitialized sections:
  - The **.bss section** reserves space for global and static variables. At boot or load time, the C boot routine or the loader copies data out of the .cinit section (which may be in ROM) and uses it for initializing variables in .bss.
  - The **.stack section** allocates memory for the system stack. This memory passes variables and is used for local storage.
  - The **.sysstack section** allocates memory for the secondary system stack.
    
    Note that the .stack and .sysstack sections must be on the same page.
  - The **.sysmem section** reserves space for dynamic memory allocation. This space is used by the malloc, calloc, and realloc functions. If a C/C++ program does not use these functions, the compiler does not create the .sysmem section.
  - The **.cio section** supports C I/O. This space is used as a buffer with the label __CIOBUF__. When any type of C I/O is performed (printf, scanf, etc.), the buffer is created. It contains an internal C I/O command (and required parameters) for the type of stream I/O that is to be performed, as well as the data being returned from the C I/O command. The .cio section must be allocated in the linker command file in order to use C I/O.

Only code sections are allowed to cross page boundaries. Any other type of section must fit on one page.
Note that the assembler creates an additional section called .data; the C/C++ compiler does not use this section.

The linker takes the individual sections from different modules and combines sections that have the same name. The resulting eight output sections and the appropriate placement in memory for each section are listed in Table 6−1. You can place these output sections anywhere in the address space, as needed to meet system requirements.

For more information about allocating sections into memory, see the Introduction to Common Object File Format chapter, in the TMS320C55x Assembly Language Tools User’s Guide.

6.1.5 C/C++ System Stack

The C/C++ compiler uses a stack to:

- Allocate local variables
- Pass arguments to functions
- Save the processor status

The run-time stack is allocated in a single continuous block of memory and grows down from high addresses to lower addresses. The compiler uses the hardware stack pointer (SP) to manage the stack.

The code does not check to see if the run-time stack overflows. Stack overflow occurs when the stack grows beyond the limits of the memory space that was allocated for it. Be sure to allocate adequate memory for the stack.

C55x also supports a secondary system stack. For compatibility with C54x, the primary run-time stack holds the lower 16 bits of addresses. The secondary system stack holds the upper 8 bits of C55x return addresses. The compiler uses the secondary stack pointer (SSP) to manage the secondary system stack.
The size of both stacks is set by the linker. The linker also creates global symbols, __STACK_SIZE and __SYSSTACK_SIZE, and assigns them a value equal to the respective sizes of the stacks in bytes. The default stack size is 1000 bytes. The default secondary system stack size is also 1000 bytes. You can change the size of either stack at link time by using the −stack or −sysstack options on the linker command line and specifying the size as a constant immediately after the option.

Note: Placement of .stack and .sysstack Sections
The .stack and .sysstack sections must be on the same page.

6.1.6 Dynamic Memory Allocation
The run-time-support library supplied with the compiler contains several functions (such as malloc, calloc, and realloc) that allow you to dynamically allocate memory for variables at run time. Dynamic allocation is provided by standard run-time-support functions.

Memory is allocated from a global pool or heap that is defined in the .sysmem section. You can set the size of the .sysmem section by using the −heap size option with the linker command. The linker also creates a global symbol, __SYSEMEM_SIZE, and assigns it as a value equal to the size of the heap in bytes. The default size is 2000 bytes. For more information on the −heap option, see section 4.2, Linker Options, on page 4-5.

Dynamically allocated objects are not addressed directly (they are always accessed with pointers), and the memory pool is in a separate section (.sysmem); therefore, the dynamic memory pool can have a size limited only by the amount of available memory in your heap. To conserve space in the .bss section, you can allocate large arrays from the heap instead of defining them as global or static. For example, instead of a definition such as:

```
struct big table [100];
```

You can use a pointer and call the malloc function:

```
struct big *table;

table = (struct big *)malloc(100*sizeof (struct big));
```

6.1.7 Initialization of Variables
The C/C++ compiler produces code that is suitable for use as firmware in a ROM-based system. In such a system, the initialization tables in the .cinit section are stored in ROM. At system initialization time, the C/C++ boot routine
copies data from these tables (in ROM) to the initialized variables in .bss (RAM).

In situations where a program is loaded directly from an object file into memory and run, you can avoid having the .cinit section occupy space in memory. A loader can read the initialization tables directly from the object file (instead of from ROM) and perform the initialization directly at load time instead of at run time. You can specify this to the linker by using the --cr linker option. For more information, see section 6.9, System Initialization, on page 6-45.
6.1.8 Allocating Memory for Static and Global Variables

A unique, contiguous space is allocated for all external or static variables declared in a C/C++ program. The linker determines the address of the space. The compiler ensures that space for these variables is allocated in multiples of words so that each variable is aligned on a word boundary.

The C/C++ compiler expects global variables to be allocated into data memory. (It reserves space for them in .bss.) Variables declared in the same module are allocated into a single, contiguous block of memory.

6.1.9 Field/Structure Alignment

When the compiler allocates space for a structure, it allocates as many words as are needed to hold all of the structure’s members.

When a structure contains a 32-bit (long) member, the long is aligned to a 2-word (32-bit) boundary. This may require padding before, inside, or at the end of the structure to ensure that the long is aligned accordingly and that the sizeof value for the structure is an even value.

All non-field types are aligned on word boundaries. Fields are allocated as many bits as requested. Adjacent fields are packed into adjacent bits of a word, but they do not overlap words; if a field would overlap into the next word, the entire field is placed into the next word. Fields are packed as they are encountered; the most significant bits of the structure word are filled first.

Example 6−1 shows the C code definition and memory layout of “var.”
Example 6–1. Field/Structure Alignment of “Var”

(a) C code definition of “var”

```c
struct example {
    char c;
    long l;
    int bf1:1;
    int bf2:2;
    int bf3:3;
    int bf4:4;
    int bf5:5;
    int bf6:6;
};
```

(b) Memory layout of “var”

<table>
<thead>
<tr>
<th>var + 0</th>
<th>var + 1</th>
<th>var + 2</th>
<th>var + 3</th>
<th>var + 4</th>
<th>var + 5</th>
</tr>
</thead>
<tbody>
<tr>
<td>char c</td>
<td>&lt;unused alignment padding&gt;</td>
<td>long l</td>
<td>&lt;unused padding&gt;</td>
<td>1</td>
<td>2</td>
</tr>
</tbody>
</table>
6.2 Character String Constants

In C, a character string constant can be used in one of the following ways:

- To initialize an array of characters. For example:

  ```c
  char s[] = "abc";
  ```

  When a string is used as an initializer, it is simply treated as an initialized array; each character is a separate initializer. For more information about initialization, see section 6.9, System Initialization, on page 6-45.

- In an expression. For example:

  ```c
  strcpy (s, "abc");
  ```

  When a string is used in an expression, the string itself is defined in the .const section with the .string assembler directive, along with a unique label that points to the string; the terminating 0 byte is included. The following example defines the string abc, along with the terminating byte; the label SL5 points to the string:

  ```assembly
  .const
  SL5: .string "abc", 0
  ```

  String labels have the form SLn, where n is a number assigned by the compiler to make the label unique. The number begins with 1 and is increased by 1 for each string defined. All strings used in a source module are defined at the end of the compiled assembly language module.

  The label SLn represents the address of the string constant. The compiler uses this label to reference the string in the expression.

  Because strings are stored in a text section (possibly in ROM) and are potentially shared, it is bad practice for a program to modify a string constant. The following code is an example of incorrect string use:

  ```c
  char *a = "abc";
  a[1] = 'x';  /* Incorrect! */
  ```
6.3 Register Conventions

Strict conventions associate specific registers with specific operations in the C/C++ environment. If you plan to interface an assembly language routine to a C/C++ program, you must understand and follow these register conventions.

The register conventions dictate how the compiler uses registers and how values are preserved across function calls. Table 6–2 describes how the registers are used and how they are preserved. The parent function is the function making the function call. The child function is the function being called. For more information about how values are preserved across calls, see section 6.4, *Function Structure and Calling Conventions*, on page 6-16.

Registers not used by compiled code are not listed in the table. Registers are used in compiled code at your discretion if their use is not specified in the table.

† The SP is preserved by the convention that everything pushed on the stack is popped off before returning.
‡ In small memory model, all extension bits of addressing registers (XARn, XCDP, and XDP) are child-saved and presumed to contain the page number of the page containing the program data.
6.3.1 Status Registers

Table 6−3 shows the status register fields.

The Presumed Value column contains the value that meets one of these conditions:

- The compiler expects in that field upon entry to, or return from, a function.
- An assembly function can expect when the function is called from C/C++ code.
- An assembly function must set upon returning to, or making a call into, C/C++ code. If this is not possible, the assembly function cannot be used with C/C++ functions.

A dash (−) in this column indicates the compiler does not expect a particular value.

The Modified column indicates whether code generated by the compiler ever modifies this field.

The run-time initialization code (boot.asm) sets the assumed values. For more information on boot.asm, see section 6.9, System Initialization, on page 6-45.

6.4 Function Structure and Calling Conventions

The C/C++ compiler imposes a strict set of rules on function calls. Except for special run-time-support functions, any function that calls or is called by a C function must follow these rules. Failure to adhere to these rules can disrupt the C/C++ environment and cause a program to fail.

Figure 6–1 illustrates a typical function call. In this example, parameters are passed to the function, and the function uses local variables and calls another function. Up to 10 parameters are passed in registers. This example also shows allocation of a local frame and argument block for the called function. The stack must be aligned to a 32-bit (even 16-bit word) boundary before calling a function. The parent function pushes the 16-bit return PC.

The term argument block refers to the part of the local frame used to pass arguments to other functions. Parameters are passed to a function by moving them into the argument block rather than pushing them on the stack. The local frame and argument block are allocated at the same time.

Figure 6–1. Use of the Stack During a Function Call
6.4.1 How a Function Makes a Call

A function (parent function) performs the following tasks when it calls another function. A C routine should be accessed with a call (CALL) instruction and never with a branch (B) instruction.

1) Arguments to a function are placed in registers or on the stack.

   a) For a function declared with an ellipsis (indicating that it is called with varying numbers of arguments), the last explicitly-declared argument is passed on the stack, followed by the rest of the arguments. Its stack address can act as a reference for accessing the undeclared arguments.

   Arguments declared before the last explicit argument follow rules shown below.

   b) In general, when an argument is passed to a function, the compiler assigns to it a particular class. It then places it in a register (if available) according to its class. The compiler uses three classes:

      - data pointer (int *, long *, etc.)
      - 16-bit data (char, short, int)
      - 32-bit data (long, float, double, function pointers) or 40-bit (long long)

      If the argument is a pointer to any type of data, it is considered a data pointer. If an argument will fit into a 16-bit register, it is considered 16-bit data. Otherwise, it is considered 32-bit data. 40-bit data is passed by using the entire register rather than just the lower 32 bits.

   c) A structure of two words (32 bits) or less is treated like a 32-bit data argument. It is passed in a register, if available.

   d) A structure larger than two words is passed by reference. The compiler will pass the address of the structure as a pointer. This pointer is treated like a data pointer argument.

   e) If the called (child) function returns a struct or union value, the parent function allocates space on the local stack for a structure of that size. The parent then passes the address of that space as a hidden first argument to the called function. This pointer is treated like a data pointer argument. In effect, the function call is transformed from:

      ```
      struct s result = fn(x, y);
      ```

      to

      ```
      fn(&result, x, y);
      ```
f) The arguments are assigned to registers in the order that the arguments are listed in the prototype. They are placed in the following registers according to their class, in the order shown below. For example, the first 32-bit data argument is placed in AC0. The second 32-bit data argument is placed in AC1, and so on.

<table>
<thead>
<tr>
<th>Argument Class</th>
<th>Assigned to Register(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>data pointer (16 or 23 bits)</td>
<td>(X)AR0, (X)AR1, (X)AR2, (X)AR3, (X)AR4</td>
</tr>
<tr>
<td>16-bit data</td>
<td>T0, T1, AR0, AR1, AR2, AR3, AR4</td>
</tr>
<tr>
<td>32-bit data or 40-bit data</td>
<td>AC0, AC1, AC2</td>
</tr>
</tbody>
</table>

The ARx registers overlap for data pointers and 16-bit data. If, for example, T0 and T1 hold 16-bit data arguments, and AR0 already holds a data pointer argument, a third 16-bit data argument would be placed in AR1. For an example, see the second prototype in Example 6–2.

If there are no available registers of the appropriate type, the argument goes on the stack.

---

**Note: C55x Calling Conventions**

The above is the default calling convention, c55_std. When using the less efficient c55_compat, the calling convention is that up to three arguments can be passed in registers. The first argument goes into either AR1 or AC0; if it is 16-bit data or a data pointer, it goes into AR1; otherwise, it goes into AC0. Similarly, the second argument goes into AR2 or AC1, and the third argument goes into AR3 or AC2.

---

g) Arguments passed on the stack are handled as follows. The stack is initially aligned to an even boundary. Then, each argument is aligned on the stack as appropriate for the argument's type (even alignment for long, long long, float, double, code pointers, and large model data pointers; no alignment for int, short, char, ioport pointers, and small model data pointers). Padding is inserted as necessary to bring arguments to the correct alignment.

2) The child function will save all of the save-on-entry registers (T2, T3, AR5–AR7). However, the parent function must save the values of the other registers, if they are needed after the call, by pushing the values onto the stack.

3) The parent calls the function.
4) The parent collects the return value.
   - Short data values are returned in T0.
   - Long data values are returned in AC0.
   - Data pointer values are returned in (X)AR0.
   - If the child returns a structure, the structure is on the local stack in the space allocated as described in step 1.

Examples of the register argument conventions are shown in Example 6–2. The registers in the examples are assigned according to the rules specified in steps 1 through 4 above.

Example 6–2. Register Argument Conventions

```c
struct big { long x[10]; };
struct small { int x; };

T0 T0 AC0 AR0
int fn(int i1, long l2, int *p3);
AC0 AR0 T0 T1 AR1
long fn(int *p1, int i2, int i3, int i4);
AR0 AR1
struct big fn(int *p1);
T0 AR0 AR1
int fn(struct big b, int *p1);
AC0 AR0
struct small fn(int *p1);
T0 AC0 AR0
int fn(struct small b, int *p1);
T0 stack stack...
int printf(char *fmt, ...);
AC0 AC1 AC2 stack T0
void fn(long l1, long l2, long l3, long l4, int i5);
AC0 AC1 AC2 AR0 AR1
void fn(long l1, long l2, long l3, int *p4, int *p5,
AR2 AR3 AR4 T0 T1
int *p6, int *p7, int *p8, int i9, int i10);
```
6.4.2 How a Called Function Responds

A called function performs the following tasks:

1) The called (child) function allocates enough space on the stack for any local variables, temporary storage areas, and arguments to functions that this function might call. This allocation occurs once at the beginning of the function.

2) If the child function modifies a save-on-entry register (T2, T3, AR5–AR7), it must save the value, either to the stack or to an unused register. The called function can modify any other register (ACx, Tx, ARx) without saving the value.

3) If the child function expects a structure argument, it receives a pointer to the structure instead. If writes are made to the structure from within the called function, space for a local copy of the structure must be allocated on the stack. The local copy of the structure must be created from the passed pointer. If no writes are made to the structure, it can be referenced in the called function indirectly through the pointer argument.

4) The child function executes the code for the function.

5) If the child function returns a value, it places the value accordingly: long data values in AC0, short data values in T0, or data pointers in (X)AR0.

   If the child returns a structure, the parent allocates space for the structure and passes a pointer to this space in (X)AR0. To return the structure, the called function copies the structure to the memory block pointed to by the extra argument.

   If the parent does not use the return structure value, an address value of 0 can be passed in (X)AR0. This directs the child function not to copy the return structure.

   You must be careful to properly declare functions that return structures, both at the point where they are called (so the caller properly sets up the first argument) and where they are defined (so the function knows to copy the result).

6) The child function restores all registers saved in step 2.

7) The child function restores the stack to its original value.

8) The function returns.
6.4.3 Accessing Arguments and Locals

The compiler uses the compiler mode (selected when the CPL bit in status register ST1_55 is set to 1) for accessing arguments and locals. When this bit is set, the direct addressing mode computes the data address by adding the constant in the dma field of the instruction to the SP. For example:

```
MOV *SP(#8), T0
```

The largest offset available with this addressing mode is 128. So, if an object is too far away from the SP to use this mode of access, the compiler copies the SP to AR6 (FP) in the function prolog, then uses long offset addressing to access the data. For example:

```
MOV SP, FP
```

```
MOV *FP(#130), AR3
```
6.5 Interfacing C/C++ With Assembly Language

The following are ways to use assembly language in conjunction with C code:

- Use separate modules of assembled code and link them with compiled C/C++ modules (see section 6.5.1). This is the most versatile method.
- Use assembly language variables and constants in C/C++ source (see section 6.5.2 on page 6-24).
- Use inline assembly language embedded directly in the C/C++ source (see section 6.5.3 on page 6-27).
- Use intrinsics in C/C++ source to directly call an assembly language statement (see section 6.5.4 on page 6-28).

6.5.1 Using Assembly Language Modules with C/C++ Code

Interfacing C/C++ with assembly language functions is straightforward if you follow the register conventions defined in section 6.3, Register Conventions, on page 6-12, and the calling conventions defined in section 6.4, Function Structure and Calling Conventions, on page 6-16. C/C++ code can access variables and call functions defined in assembly language, and assembly code can access C/C++ variables and call C/C++ functions.

Follow these guidelines to interface assembly language and C:

- You must preserve any dedicated registers modified by a function. Dedicated registers include:
  - Child-saved registers (T2, T3, AR5, AR6, AR7)
  - Stack pointer (SP)

If the SP is used normally, it does not need to be explicitly preserved. In other words, the assembly function is free to use the stack as long as anything that is pushed onto the stack is popped back off before the function returns (thus preserving SP).

Any register that is not dedicated can be used freely without first being saved.

- To call a C54x assembly function from compiled C55x code, use the C54X_CALL or C54X_FAR_CALL pragma. For more information, see section 5.7.2, The C54X_CALL and C54X_FAR_CALL Pragmas, on page 5-19.

- Interrupt routines must save all the registers they use. For more information, see section 6.6, Interrupt Handling, on page 6-38.
When calling C/C++ functions, remember that only the dedicated registers are preserved. C/C++ functions can change the contents of any other register.

The compiler assumes that the stack is initialized at run time to an even word address. If your assembly function calls a C/C++ function, you must align the SP by subtracting an odd number from the SP. The space must then be deallocated at the end of the function by adding the same number to the SP. For example:

```assembly
_func: AADD #−1, SP ; aligns SP
... ; body of function
AADD #1, SP ; deallocate stack space
RET ; return from asm function
```

Longs and floats are stored in memory with the most significant word at the lower address.

Functions must return values as described in section 6.4.2, How a Called Function Responds, on page 6-20.

No assembly language module should use the .cinit section for any purpose other than autoinitialization of global variables. The C/C++ startup routine in boot.asm assumes that the .cinit section consists entirely of initialization tables. Disrupting the tables by putting other information in .cinit causes unpredictable results.

The compiler places an underscore ( _ ) at the beginning of all identifiers. This name space is reserved by the compiler. Prefix the names of variables and functions that are accessible from C/C++ with _. For example, a C/C++ variable called x is called _x in assembly language.

For identifiers that are to be used only in an assembly language module or modules, the identifier should not begin with an underscore.

Any object or function declared in assembly language that is to be accessed or called from C/C++ must be declared with the .global directive in the assembler. This defines the symbol as external and allows the linker to resolve references to it.

Likewise, to access a C/C++ function or object from assembly language, declare the C/C++ object with .global. This creates an undefined external reference that the linker resolves.

Because compiled code runs with the CPL (compiler mode) bit set to 1, the only way to access directly addressed objects is with indirect absolute mode. For example:

```assembly
MOV *(#global_var), AR3 ; works with CPL = 1
MOV global_var, AR3     ; does not work with CPL ==1
```
If you set the CPL bit to 0 in your assembly language function, you must set it back to 1 before returning to compiled code.

**Example 6–3. Calling an Assembly Language Function From C**

(a) *C program*

```c
extern void asmfunc(int *);
int global;

void func()
{
    int local = 5;
    asmfunc(&local);
}
```

(b) *Assembly language output*

```asm
_func:
    AADD #−1, SP
    MOV XSP, XAR0
    MOV #5, *SP(#0)
    CALL #_asmfunc
    AADD #1, SP
    RET
```

(c) *Assembly language source code for asmfunc*

```asm
_asmfunc:
    MOV *AR0, AR1
    ADD *(_global), AR1, AR1
    MOV AR1, *(_global)
    RET
```

In the assembly language code in Example 6–3, note the underscore on the C/C++ symbol name used in the assembly code.

### 6.5.2 Accessing Assembly Language Variables From C/C++

It is sometimes useful for a C/C++ program to access variables defined in assembly language. There are three methods that you can use to accomplish this, depending on where and how the item is defined: a variable defined in the .bss section, a variable not defined in the .bss section, or a constant.
6.5.2.1 Accessing Assembly Language Global Variables

Accessing uninitialized variables from the .bss section or a section named with .usect is straightforward:

1) Use the .bss or .usect directive to define the variable.
2) Use the .global directive to make the definition external.
3) Precede the name with an underscore in assembly language.
4) In C/C++, declare the variable as extern and access it normally.

Example 6−4 shows how you can access a variable defined in .bss from C.

Example 6−4. Accessing a Variable From C

(a) Assembly language program

```assembly
* Note the use of underscores in the following lines
.bss _var,1 ; Define the variable
.global _var ; Declare it as external
```

(b) C program

```c
extern int var; /* External variable */
var = 1; /* Use the variable */
```

You may not always want a variable to be in the .bss section. For example, a common situation is a lookup table defined in assembly language that you do not want to put in RAM. In this case, you must define a pointer to the object and access it indirectly from C/C++.

The first step is to define the object; it is helpful (but not necessary) to put it in its own initialized section. Declare a global label that points to the beginning of the object, and then the object can be linked anywhere into the memory space. To access it in C/C++, you must declare the object as extern and not precede it with an underscore. Then you can access the object normally.

Example 6−5 shows an example that accesses a variable that is not defined in .bss.
Example 6–5. Accessing from C a Variable Not Defined in .bss

(a) C Program

```c
extern float sine[];  /* This is the object */
float *sine_p = sine; /* Declare pointer to point to it */
f = sine_p[4];       /* Access sine as normal array */
```

(b) Assembly Language Program

```assembly
.global _sine       ; Declare variable as external
.sect    "sine_tab"  ; Make a separate section
._sine:                  ; The table starts here
    .float   0.0
    .float   0.015987
    .float   0.022145
```

6.5.2.2 Accessing Assembly Language Constants

You can define global constants in assembly language by using the .set and .global directives, or you can define them in a linker command file using a linker assignment statement. These constants are accessible from C/C++ only with the use of special operators.

For normal variables defined in C/C++ or assembly language, the symbol table contains the address of the value of the variable. For assembler constants, however, the symbol table contains the value of the constant. The compiler cannot tell which items in the symbol table are values and which are addresses.

If you try to access an assembler (or linker) constant by name, the compiler attempts to fetch a value from the address represented in the symbol table. To prevent this unwanted fetch, you must use the & (address of) operator to get the value. In other words, if x is an assembly language constant, its value in C/C++ is &x.

You can use casts and #defines to ease the use of these symbols in your program, as in Example 6–6.
Example 6–6. Accessing an Assembly Language Constant From C

(a) Assembly language program

```
_table_size .set 10000 ; define the constant
.global _table_size ; make it global
```

(b) C program

```
extern int table_size; /* external ref */
#define TABLE_SIZE ((int) (&table_size))
    . /* use cast to hide address-of */
    .
    .
for (i=0; i<TABLE_SIZE; ++i)
    . /* use like normal symbol */
```

Since you are referencing only the symbol’s value as stored in the symbol table, the symbol’s declared type is unimportant. In Example 6–6, int is used. You can reference linker-defined symbols in a similar manner.

6.5.3 Using Inline Assembly Language

Within a C/C++ program, you can use the `asm` statement to insert a single line of assembly language into the assembly language file created by the compiler. A series of `asm` statements places sequential lines of assembly language into the compiler output with no intervening code. For more information, see section 5.6, The `asm` Statement, on page 5-16.

The `asm` statement is useful for inserting comments in the compiler output. Simply start the assembly code string with a semicolon (`;`) as shown below:

```
asm(";*** this is an assembly language comment");
```
Note: Using the asm Statement

Keep the following in mind when using the asm statement:

- Be extremely careful not to disrupt the C/C++ environment. The compiler does not check or analyze the inserted instructions.
- Inserting jumps or labels into C/C++ code can produce unpredictable results by confusing the register-tracking algorithms that the code generator uses.
- Do not change the value of a C/C++ variable when using an asm statement.
- Do not use the asm statement to insert assembler directives that change the assembly environment.

6.5.4 Using Intrinsics to Access Assembly Language Statements

The compiler recognizes a number of intrinsic operators. Intrinsics are used like functions and produce assembly language statements that would otherwise be inexpressible in C/C++. You can use C/C++ variables with these intrinsics, just as you would with any normal function. The intrinsics are specified with a leading underscore, and are accessed by calling them as you do a function. For example:

```c
int x1, x2, y;
y = _sadd(x1, x2);
```

Many of the intrinsic operators support saturation. During saturating arithmetic, every expression which overflows is given a reasonable extremum value, either the maximum or the minimum value the expression can hold. For instance, in the above example, if \( x1=x2=\text{INT\_MAX} \), the expression overflows and saturates, and \( y \) is given the value \( \text{INT\_MAX} \). Saturation is controlled by setting the saturation bit, \( \text{ST1\_SATD} \), by using these instructions:

```c
BSET ST1_SATD
BCLR ST1_SATD
```

The compiler must turn this bit on and off to mix saturating and non-saturating arithmetic; however, it minimizes the number of such bit changing instructions by recognizing blocks of instructions with the same behavior. For maximum efficiency, use saturating intrinsic operators for exactly those operations where you need saturated values in case of overflow, and where overflow can occur. Do not use them for loop iteration counters.
The compiler supports associative versions for some of the addition and multiply-and-accumulate intrinsics. These associative intrinsics are prefixed with "_a_". The compiler is able to reorder arithmetic computations involving associative intrinsics, which may produce more efficient code.

For example:

```c
int x1, x2, x3, y;
y = _a_sadd(x1, _a_sadd(x2, x3)); /* version 1 */
```

can be reordered inside the compiler as:

```c
y = _a_sadd(_a_sadd(x1, x2), x3); /* version 2 */
```

However, this reordering may affect the value of the expression if saturation occurs at different points in the new ordering. For instance, if \( x1=\text{INT\_MAX} \), \( x2=\text{INT\_MAX} \), and \( x3=\text{INT\_MIN} \), version 1 of the expression will not saturate, and \( y \) will be equal to \((\text{INT\_MAX}-1)\); however, version 2 will saturate, and \( y \) will be equal to \(-1\). A rule of thumb is that if all your data have the same sign, you may safely use associative intrinsics.

Most of the multiplicative intrinsic operators operate in fractional-mode arithmetic. Conceptually, the operands are Q15 fixed-point values, and the result is a Q31 value. Operationally, this means that the result of the normal multiplication is left shifted by one to normalize to a Q31 value. This mode is controlled by the fractional mode bit, ST1_FRCT.

The intrinsics in Table 6–7 on page 6-33 are special in that they accept pointers and references to values; the arguments are passed by reference rather than by value. These values must be modifiable values (for example, variables but not constants, nor arithmetic expressions). These intrinsics do not return a value; they create results by modifying the values that were passed by reference. These intrinsics depend on the C++ reference syntax, but are still available in C code with the C++ semantics.

No declaration of the intrinsic functions is necessary, but declarations are provided in the header file, c55x.h, included with the compiler.

Many of the intrinsic operators are useful for implementing basic DSP functions described in the Global System for Mobile Communications (GSM) standard of the European Telecommunications Standards Institute (ETSI). These functions have been implemented in the header file, gsm.h, included with the compiler. Additional support for ETSI GSM functions is described in section 6.5.4.1 on page 6-35.
Table 6–4 on page 6-30 through Table 6–8 on page 6-34 list all of the intrinsic operators in the TMS320C55x C/C++ compiler. A “function” prototype is presented for each intrinsic that shows the expected type for each parameter. If the argument type does not match the parameter, type conversions are performed on the argument. Where argument order matters, the order of the intrinsic’s input arguments matches that of the underlying hardware instruction. The resulting assembly language mnemonic is given for each instruction; for some instructions, such as MPY, an alternate instruction such as SQR (which is a specialized MPY) may be generated if it is more efficient. A brief description is provided for each intrinsic. For a precise definition of the underlying instruction, see the TMS320C55x DSP Mnemonic Instruction Set Reference Guide (SPRU374) and TMS320C55x DSP Algebraic Instruction Set Reference Guide (SPRU375).

Table 6-4. C55x C/C++ Compiler Intrinsics (Addition, Subtraction, Negation, Absolute Value)

```

Interfacing C/C++ With Assembly Language

Run-Time Environment 6-37
6.6 Interrupt Handling

As long as you follow the guidelines in this section, C/C++ code can be interrupted and returned to without disrupting the C/C++ environment. When the C/C++ environment is initialized, the startup routine does not enable or disable interrupts. (If the system is initialized via a hardware reset, interrupts are disabled.) If your system uses interrupts, it is your responsibility to handle any required enabling or masking of interrupts. Such operations have no effect on the C/C++ environment and can be easily implemented with asm statements.

6.6.1 General Points About Interrupts

An interrupt routine may perform any task performed by any other function, including accessing global variables, allocating local variables, and calling other functions.

When you write interrupt routines, keep the following points in mind:

- It is your responsibility to handle any special masking of interrupts.
- An interrupt handling routine cannot have arguments.
- An interrupt handling routine cannot be called by normal C/C++ code.
- An interrupt handling routine can handle a single interrupt or multiple interrupts. The compiler does not generate code that is specific to a certain interrupt, except for c_int00, which is the system reset interrupt. When you enter c_int00, you cannot assume that the run-time stack is set up; therefore, you cannot allocate local variables, and you cannot save any information on the run-time stack.
- To associate an interrupt routine with an interrupt, a branch must be placed in the appropriate interrupt vector. You can use the assembler and linker to do this by creating a simple table of branch instructions using the .sect assembler directive.
- In assembly language, remember to precede the symbol name with an underscore. For example, refer to c_int00 as _c_int00.
- At the top of the interrupt routine, the stack might not be aligned to an even (long-aligned) address. You must write code to ensure that the stack pointer is aligned properly.

6.6.2 Saving Context on Interrupt Entry

All registers that the interrupt routine uses, including the status registers, must be preserved. If the interrupt routine calls other functions, all of the registers in Table 6–2 on page 6-13 must be preserved.
6.6.3 Using C/C++ Interrupt Routines

Interrupts can be handled directly with C/C++ functions by using the interrupt keyword. For example:

```c
interrupt void isr()
{
    ...
}
```

Adding the interrupt keyword defines an interrupt routine. When the compiler encounters one of these routines, it generates code that allows the function to be activated from an interrupt trap, performing the necessary stack alignment and context save. This method provides more functionality than the standard C/C++ signal mechanism, which is not implemented in the C55x library. This does not prevent implementation of the signal function, but it does allow these functions to be written entirely in C/C++.

6.6.4 Intrinsics for Interrupts

Two intrinsics support enabling and disabling interrupts from C. They are defined in the file c55x.h and are the following:

```c
void _enable_interrupts(void);
void _disable_interrupts(void);
```

These functions compile into instructions that clear (for enable) or set (for disable) the INTM bit in the ST1 status register.

On some versions of the hardware there is a latency between setting the INTM bit and when interrupts are actually disabled. The compiler manages this latency by scheduling the instruction that sets INTM an appropriate number of cycles before the point where _disable_interrupts() appears in the source code. (The actual point at which interrupts are disabled is indicated by an interrupts disabled comment in the compiler’s assembly output.)

Using these intrinsics not only allows you to enable and disable the interrupts with C code but guarantees that any necessary timing issues are handled automatically.
6.7 Extended Addressing of Data in P2 Reserved Mode

The run-time library includes functions to support reading and writing of data in the full TMS320C55x address space. These functions may be accessed via extaddr.h, shown in Figure 6–3. Extended memory addresses are represented by values of the integer type FARPTR (unsigned long). An extended addressing code example is shown in Example 6–8 on page 6-43.

When using P2 Restricted Mode hardware all C-accessible data objects must reside on the 64K-word data page zero.

Run-time functions have been added to support copying data to and from remote data pages and page zero. Full, 23-bit addresses passed to these functions are represented as unsigned long integer values.

The .cinit sections and .switch sections can be placed in extended memory. However, .const sections cannot be placed in extended memory. For more information, see section 6.8, .const Sections in Extended Memory, on page 6-43.

Figure 6–3. The File extaddr.h

```c
/* extaddr.h *
**********************************************************************/
/* Type of extended memory data address values */
 /**********************************************************************/
typedef unsigned long FARPTR;

!important Prototypes for Extended Memory Data Support Functions */
/* */
/* far_peek Read an int from extended memory address */
/* far_peek_l Read an unsigned long from extended memory address */
/* far_poke Write an int to extended memory address */
/* far_poke_l Write an unsigned long to extended memory address */
/* far_memcpy Block copy between extended memory addresses */
/* far_near_memcpy Block copy from extended memory address to page 0 */
/* near_far_memcpy Block copy from page 0 to extended memory address */
!/**********************************************************************/
int far_peek(FARPTR);
unsigned long far_peek_l(FARPTR);
void far_poke(FARPTR, int);
void far_poke_l(FARPTR, unsigned long);
void far_memcpy(FARPTR, FARPTR, int);
void far_near_memcpy(void *, FARPTR, int);
void near_far_memcpy(FARPTR, void *, int);
```
6.7.1 Placing Data in Extended Memory

Global and static C variables can be placed in extended memory. Use the DATA_SECTION pragma to place them in a particular named section. Then edit your linker control file to place that named section in extended memory.

You can access such variables only by using the functions described in section 6.7. Use of such variables in normal C expressions leads to unpredictable results.

Global and static variables placed in extended memory can be initialized in the C source code as usual. The autoinitiation of these variables is supported in the same manner as other global and static variables.

6.7.2 Obtaining the Full Address of a Data Object in Extended Memory

The pragma FAR is used to obtain the full, 23-bit address of a data object declared at file scope. The pragma must immediately precede the definition of the symbol to which it applies as shown below:

```c
#pragma FAR(x)
int x;         /* ok */
#pragma FAR(z)
int y;         /* error - z’s definition must immediately follow #pragma */
int z;         /* ok */
```

This pragma can only be applied to objects declared at file scope. Once this is done, taking the address of the indicated object produces the 23-bit value that is the full address of the object. This value may be cast to FARPTR (that is, unsigned long) and passed to the run-time support functions. For a structured object taking the address of a field also produces a full address.
6.7.3 Accessing Far Data Objects

Support for accessing far data objects is not general. Declaring an object with the FAR pragma does not cause the compiler to treat it as far for any construct other than taking its address (as shown in Example 6–7). For example, there are no far pointer types and far objects cannot be accessed directly (as in \( i = \text{ary}[10] \)). The compiler does not diagnose these transgressions.

Example 6–7. Idiom for Accessing a Far Object

```c
#include <extaddr.h>

#pragma DATA_SECTION(var, ".far_data")
#pragma FAR(var)
int var;

#pragma DATA_SECTION(ary, ".far_data")
#pragma FAR(ary)
int ary[100];
...

void func(void)
{
    /* Save pointer to ary */
    FARPTR aptr = (FARPTR) &ary;
    ...

    /* Load page zero from extended memory */
    i = far.peek((FARPTR) &var);
    far_near_copy(&data, aptr, 100);
    ...
```
6.8 The .const Sections in Extended Memory

Unlike .cinit and .switch sections, .const sections cannot be placed in extended memory. However, the −mc shell option allows constants normally placed in a .const section to be treated as read-only, initialized static variables. This allows the constant values to be loaded into extended memory while the space used to hold the values at run time is still in page 0.

The space used to hold the constant is allocated in a .bss section. An autoinitialization record used to initialize the constant is allocated in a .cinit section. Autoinitialization places the constant value into the location in the .bss section in the same way as it does for the initialization of the global and static variables.

A constant explicitly placed in a named section via the DATA_SECTION pragma is not affected by the −mc option. It will be placed in the named section, not in a .cinit record for initialization.

Example 6–8. Extended Addressing of Data

```c
#include <extaddr.h>

/**************************
* Variables to be placed in extended memory. *
**************************/

#pragma DATA_SECTION(ival, ".far_data")
#pragma FAR(ival)
int ival;

#pragma DATA_SECTION(lval, ".far_data")
#pragma FAR(lval)
unsigned long lval;

#pragma DATA_SECTION(a, ".far_data")
#pragma FAR(a)
int a[10] = {0,1,2,3,4,5,6,7,8,9};

#pragma DATA_SECTION(b, ".far_data")
#pragma FAR(b)
int b[10];

#pragma DATA_SECTION(c, ".far_data")
#pragma FAR(c)
char c[12] = {"test string"};
```
Example 6–8. Example of Extended Addressing of Data (Continued)

```c
/************************************************************/
Variable to be placed in memory page 0.
/************************************************************/
char d[12];

void main(void)
{
  int ilocal;

  /* Get extended addresses of variables */
  FARPTR iptr = (FARPTR) &ival;
  FARPTR lptr = (FARPTR) &lval;

  /* Read and write variables in extended memory */
  /* ival = 100 */
  far_poke(iptr, 100);
  /* ival += 10 */
  ilocal = far_peek(iptr) + 10;
  far_poke(iptr, ilocal);
  /* lval = 0x7ffffffe */
  far_poke_l(lptr, 0x7ffffffe);
  /* lval += 1 */
  far_poke_l(lptr, far_peek_l(lptr) + 1);

  /* Copy string from extended data memory to an address in Page 0. */
  far_near_memcpy((void *) d, (FARPTR) &c, 12);

  /* Copy an array of integers from one extended address to another extended address. */
  far_memcpy((FARPTR) &b, (FARPTR) &a, 10);
}
```
6.9 System Initialization

Before you can run a C/C++ program, the C/C++ run-time environment must be created. This task is performed by the C/C++ boot routine, which is a function called _c_int00. The run-time-support source library (rts.src) contains the source to this routine in a module called boot.asm.

To begin running the system, the _c_int00 function can be called by reset hardware. You must link the _c_int00 function with the other object modules. This occurs automatically when you use the −c or −cr linker function option and include rts.src as one of the linker input files.

When C/C++ programs are linked, the linker sets the entry point value in the executable output module to the symbol _c_int00. The _c_int00 function performs the following tasks to initialize the C/C++ environment:

1) Sets up the stack and the secondary system stack.

2) Initializes global variables by copying the data from the initialization tables in the .cinit and .pinit sections to the storage allocated for the variables in the .bss section. If initializing variables at load time (−cr option), a loader performs this step before the program runs (it is not performed by the boot routine). For information, see section 6.9.1, Automatic Initialization of Variables, on page 6-45.

3) Calls the function main to begin running the C/C++ program.

You can replace or modify the boot routine to meet your system requirements. However, the boot routine must perform the operations listed above to correctly initialize the C/C++ environment.

For additional information on the boot routine, see section 4.3.2, Run-Time Initialization, on page 4-9.

6.9.1 Automatic Initialization of Variables

Any global variables declared as preinitialized must have initial values assigned to them before a C/C++ program starts running. The process of retrieving these variables’ data and initializing the variables with the data is called autoinitialization.

The compiler builds tables that contain data for initializing global and static variables in a .cinit section in each file. Each compiled module contains these initialization tables. The linker combines them into a single table (a single .cinit section). The boot routine or loader uses this table to initialize all the system variables.
**Note: Initializing Variables**

In ISO C, global and static variables that are not explicitly initialized must be set to 0 before program execution. The C/C++ compiler does not perform any preinitialization of uninitialized variables. You must explicitly initialize any variable that must have an initial value of 0.

The easiest method is to set a fill value of zero in the linker control map for the .bss section. (You cannot use this method with code that is burned into ROM.)

---

**6.9.2 Global Object Constructors**

All global C++ variables that have constructors must have their constructor called before main(). The compiler builds a table of global constructor addresses that must be called, in order, before main() in a section called .pinit. The linker combines the .pinit section from each input file to form a single table in the .pinit section. The boot routine uses this table to execute the constructors.

**6.9.3 Initialization Tables**

The tables in the .cinit section consist of variable-size initialization records. Each variable that must be autoinitialized has a record in the .cinit section. Figure 6–4 shows the format of the .cinit section and the initialization records.

**Figure 6–4. Format of Initialization Records in the .cinit Section**

An initialization record contains the following information:

- The first field (word 0) contains the size in words of the initialization data. Bits 14 and 15 are reserved. An initialization record can be up to $2^{13}$ words in length.
The second field contains the starting address of the area in the .bss section where the initialization data must be copied. This field is 24 bits to accommodate an address greater than 16 bits.

The third field contains 8 bits of flags. Bit 0 is a flag for the memory space indicator (I/O or data). The other bits are reserved.

The fourth field (words 3 through n) contains the data that is copied to initialize the variable.

The .cinit section contains an initialization record for each variable that is initialized. Example 6–9 (a) shows initialized variables defined in C/C++. Example 6–9 (b) shows the corresponding initialization table.

Example 6–9. Initialization Variables and Initialization Table

(a) Initialized variables defined in C

```c
int i = 3;
long x = 4;
float f = 1.0;
char s[] = "abcd";
long a[5] = { 1, 2, 3, 4, 5 };
```
Example 6–9. Initialization Variables and Initialization Table (Continued)

(b) Initialized information for variables defined in (a)

```
.sect ".cinit" ; Initialization section
* Initialization record for variable i
  .field 1,16 ; length of data (1 word)
  .field _i+0,24 ; address in .bss
  .field 0,8 ; signifies data memory
  .field 3,16 ; int is 16 bits
* Initialization record for variable x
  .field 2,16 ; length of data (2 words)
  .field _l+0,24 ; address in .bss
  .field 0,8 ; data memory
  .field 4,32 ; long is 32 bits
* Initialization record for variable f
  .field 2,16 ; length of data (2 words)
  .field _f+0,24 ; address in .bss
  .field 0,8 ; data memory
  .xlong 0x3f800000 ; float is 32 bits
* Initialization record for variable s
  .field IR_1,16 ; length of data
  .field _s+0,24 ; address in .bss
  .field 0,8 ; data memory
  .field 97,16 ; a
  .field 98,16 ; b
  .field 99,16 ; c
  .field 100,16 ; d
  .field 0,16 ; end of string
IR_1 .set 5 ; symbolic value gives
           ; count of elements
* Initialization record for variable a
  .field IR_2,16 ; length of data
  .field _a+0,24 ; address in .bss
  .field 0,8 ; data memory
  .field 1,32 ; beginning of array
  .field 2,32
  .field 3,32
  .field 4,32
  .field 5,32 ; end of array
IR_2 .set 10 ; size of array
```

The .cinit section must contain only initialization tables in this format. If you interface assembly language modules to your C/C++ programs, do not use the .cinit section for any other purpose.

When you use the −c or −cr option, the linker combines the .cinit sections from all the C modules and appends a null word to the end of the composite .cinit section. This terminating record appears as a record with a size field of 0 and marks the end of the initialization tables.
Likewise, the −c or −cr linker option causes the linker to combine all of the .pinit sections from all the C/C++ modules and appends a null word to the end of the composite .pinit section. The boot routine knows the end of the global constructor table when it encounters a null constructor address.

Note that const-qualified variables are initialized differently; see section 5.9.2, Initializing Static and Global Variables with the Const Type Qualifier, on page 5-34.

6.9.4 Autoinitialization of Variables at Run Time

Autoinitializing variables at run time is the default model for autoinitialization. To use this method, invoke the linker with the −c option.

Using this method, the .cinit section is loaded into memory (possibly ROM) along with all the other initialized sections, and global variables are initialized at run time. The linker defines a special symbol called cinit that points to the beginning of the initialization tables in memory. When the program begins running, the C/C++ boot routine copies data from the tables (pointed to by cinit) into the specified variables in the .bss section. This allows initialization data to be stored in ROM and copied to RAM each time the program starts.

Figure 6-6 illustrates autoinitialization at run time. Use this method in any system where your application runs from code burned into ROM.
6.9.5 Initialization of Variables at Load Time

Autoinitialization of variables at load time enhances performance by reducing boot time and by saving the memory used by the initialization tables. To use this method, invoke the linker with the −cr option.

When you use the –cr linker option, the linker sets the STYP_COPY bit in the .cinit section’s header. This tells the loader not to load the .cinit section into memory. (The .cinit section occupies no space in the memory map.) The linker also sets the cinit symbol to −1 (normally, cinit points to the beginning of the initialization tables). This indicates to the boot routine that the initialization tables are not present in memory; accordingly, no run-time initialization is performed at boot time.

A loader (which is not part of the compiler package) must be able to perform the following tasks to use autoinitialization at load time:

- Detect the presence of the .cinit section in the object file
- Determine that STYP_COPY is set in the .cinit section header, so that it knows not to copy the .cinit section into memory
- Understand the format of the initialization tables

Figure 6–7 illustrates the RAM model of autoinitialization.
Figure 6–7. Initialization at Load Time
Some of the tasks that a C/C++ program performs (such as I/O, dynamic memory allocation, string operations, and string searches) are not part of the C/C++ language itself. The run-time-support functions, which are included with the C/C++ compiler, are standard ISO functions that perform these tasks.

The run-time-support library, rts.src, contains the source for these functions as well as for other functions and routines. All of the ISO functions except those that require an underlying operating system (such as signals) are provided.

A library-build utility is included with the code generation tools that lets you create customized run-time-support libraries. For information about using the library-build utility, see Chapter 8, Library-Build Utility.

7.1 Libraries

The following libraries are included with the TMS320C55x C/C++ compiler:

- `rts55.lib` contains the ISO run-time-support object library
- `rts55x.lib` contains the ISO run-time-support object library for the large memory model
- `rts.src` contains the source for the ISO run-time-support routines

The object library includes the standard C/C++ run-time-support functions described in this chapter, the floating-point routines, and the system startup routine, `_c_int00`. The object library is built from the C/C++ and assembly source contained in `rts.src`.

When you link your program, you must specify an object library as one of the linker input files so that references to the I/O and run-time-support functions can be resolved.

You should specify libraries last on the linker command line because the linker searches a library for unresolved references when it encounters the library on the command line. You can also use the `-x` linker option to force repeated searches of each library until the linker can resolve no more issues.

When a library is linked, the linker includes only those library members required to resolve undefined references. For more information about linking, see the linker description chapter of the *TMS320C55x Assembly Language Tools User's Guide*.
7.1.1 Modifying a Library Function

You can inspect or modify library functions by using the archiver to extract the appropriate source file or files from rts.src. For example, the following command extracts two source files:

```
ar55 x rts.src atoi.c strcpy.c
```

To modify a function, extract the source as in the previous example. Make the required changes to the code, recompile, and reinstall the new object file(s) into the library:

```
c55 -options atoi.c strcpy.c ;recompile
ar55 -r rts.src atoi.c strcpy.c ;rebuild library
```

You can also build a new library this way, rather than rebuilding into rts55.lib. For more information about the archiver, see the archiver description chapter of the TMS320C55x Assembly Language Tools User’s Guide.

7.1.2 Building a Library With Different Options

You can create a new library from rts.src by using the library-build utility, mk55. For example, use this command to build an optimized run-time-support library:

```
mk55 --u -o2 rts.src -l rts55.lib
```

The --u option tells the mk55 utility to use the header files in the current directory, rather than extracting them from the source archive. The use of the optimizer (-o2) option does not affect compatibility with code compiled without this option. For more information about building libraries, see Chapter 8, Library-Build Utility.
7.2 The C I/O Functions

The C I/O functions make it possible to access the host's operating system to perform I/O (using the debugger). For example, printf statements executed in a C55x program appear in the debugger command window. When used in conjunction with the debugging tools, the capability to perform I/O on the host gives you more options when debugging and testing code.

To use the I/O functions, include the header file stdio.h for each module that references a function.

To use the I/O functions, include the header file stdio.h, or cstdio for C++ code, for each module that references a function.

If you do not use TI's default linker command file, you should allocate the .cio section in your linker command file. The .cio section provides a buffer (with the label __CIOBUF_) that is used by the run-times and the debugger. When any type of C I/O is performed (printf, scanf, etc.), the buffer is created and placed at the __CIOBUF_ address. The buffer contains:

- An internal C I/O command (and required parameters) for the type of stream I/O that is to be performed.
- The data being returned from the I/O command.

The buffer will be read by the debugger, and the debugger will perform the appropriate I/O command.

For example, given the following program in a file named main.c:

```c
#include <stdio.h>
main()
{
    FILE *fid;
    fid = fopen("myfile","w");
    fprintf(fid,"Hello, world\n");
    fclose(fid);
    printf("Hello again, world\n");
}
```

Issuing the following shell command compiles, links, and creates the file main.out:

```
c155 main.c -z -heap 400 -l rts.lib -o main.out
```
Executing main.out under the C55x debugger on a SPARC host accomplishes the following:

1) Opens the file *myfile* in the directory where the debugger was invoked
2) Prints the string *Hello, world* into that file
3) Closes the file
4) Prints the string *Hello again, world* in the debugger command window

With properly written device drivers, the functions also offer facilities to perform I/O on a user-specified device.

If there is not enough space on the heap for a C I/O buffer, buffered operations on the file will fail. If a call to printf() mysteriously fails, this may be the reason. Check the size of the heap. To set the heap size, use the −heap option when linking.
7.2.1 Overview of Low-Level I/O Implementation

The code that implements I/O is logically divided into three layers: high-level, low-level, and device-level.

The high-level functions are the standard C library of stream I/O routines (printf, scanf, fopen, getchar, etc.). These routines map an I/O request to one or more of the I/O commands that are handled by the low-level shell.

The low-level functions are comprised of basic I/O functions: open, read, write, close, lseek, rename, and unlink. These low-level functions provide the interface between the high-level functions and the device-level drivers that actually perform the I/O command on the specified device.

The low-level functions also define and maintain a stream table that associates a file descriptor with a device. The stream table interacts with the device table to ensure that an I/O command performed on a stream executes the correct device-level routine.

The data structures interact as shown in Figure 7–1.

Figure 7–1. Interaction of Data Structures in I/O Functions
The first three streams in the stream table are predefined to be stdin, stdout, and stderr, and they point to the host device and associated device drivers.

Figure 7-2. The First Three Streams in the Stream Table

At the next level are the user-definable device-level drivers. They map directly to the low-level I/O functions. The C I/O library includes the device drivers necessary to perform C I/O on the host on which the debugger is running.

The specifications for writing device-level routines so that they interface with the low-level routines are described on pages 7-12 through 7-15. You should write each function to set up and maintain its own data structures as needed. Some function definitions perform no action and should just return.

7.2.2 Adding a Device For C I/O

The low-level functions provide facilities that allow you to add and use a device for I/O at run time. The procedure for using these facilities is:

1) Define the device-level functions as described in section 7.2.1 on page 7-6.

Note: Use Unique Function Names

The function names open(), close(), read(), etc. have been used by the low-level routines. Use other names for the device-level functions that you write.

2) Use the low-level function add_device() to add your device to the device_table. The device table is a statically defined array that supports \( n \) devices, where \( n \) is defined by the macro _NDEVICE found in file.h. The structure representing a device is defined in lowlev.c and is composed of the following fields:
name String for device name
flags Specifies whether device supports multiple streams or not
function pointers Pointers to the device-level functions:
- close
- lseek
- open
- read
- rename
- write
- unlink

The first entry in the device table is predefined to be the host device on which the debugger is running. The low-level routine add_device() finds the first empty position in the device table and initializes the device fields with the passed in arguments. For a complete description of the add_device function, see page 7-10.

3) Once the device is added, call fopen() to open a stream and associate it with that device. Use devicename:filename as the first argument to fopen().
The following program illustrates adding and using a device for C I/O:

```c
#include <stdio.h>
#include <file.h>
/****************************************************************************
/* Declarations of the user−defined device drivers                     */
/****************************************************************************
extern int my_open(char *path, unsigned flags, int fno);
extern int my_close(int fno);
extern int my_read(int fno, char *buffer, unsigned count);
extern int my_write(int fno, char *buffer, unsigned count);
extern off_t my_lseek(int fno, off_t offset, int origin);
extern int my_unlink(char *path);
extern int my_rename(char *old_name, char *new_name);
main()
{
    FILE *fid;
    add_device("mydevice", _MSA, my_open, my_close, my_read, my_write,
               my_lseek, my_unlink, my_rename);
    fid = fopen("mydevice:test","w");
    fprintf(fid,"Hello, world\n");
    fclose(fid);
}
```
add_device

Add Device to Device Table

Syntax

```c
#include < file.h >
int add_device(char *name,
               unsigned flags,
               int (*dopen)(),
               int (*dclose)(),
               int (*dread)(),
               int (*dwrite)(),
               off_t (*dlseek)(),
               int (*dunlink)(),
               int (*drename)());
```

Defined in

lowlev.c in rts.src

Description

The `add_device` function adds a device record to the device table allowing that device to be used for input/output from C. The first entry in the device table is predefined to be the host device on which the debugger is running. The function `add_device()` finds the first empty position in the device table and initializes the fields of the structure that represent a device.

To open a stream on a newly-added device, use `fopen()` with a string of the format `devicename:filename` as the first argument.

- The `name` is a character string denoting the device name.
- The `flags` are device characteristics. The flags are as follows:
  - \_SSA Denotes that the device supports only one open stream at a time
  - \_MSA Denotes that the device supports multiple open streams

More flags can be added by defining them in stdio.h.

- The `dopen`, `dclose`, `dread`, `dwrite`, `dlseek`, `dunlink`, `drename` specifiers are function pointers to the device drivers that are called by the low-level functions to perform I/O on the specified device. You must declare these functions with the interface specified in section 7.2.1, *Overview of Low-Level I/O Implementation*, on page 7-6. The device drivers for the host that the debugger is run on are included in the C I/O library.

Return Value

The function returns one of the following values:

- 0 if successful
- -1 if fails
Example

This example does the following:

- Adds the device *mydevice* to the device table
- Opens a file named *test* on that device and associates it with the file *fid*
- Prints the string *Hello, world* into the file
- Closes the file

```c
#include <stdio.h>

/**************************************************************************/
/* Declarations of the user-defined device drivers */
/**************************************************************************/
extern int my_open(const char *path, unsigned flags, int fno);
extern int my_close(int fno);
extern int my_read(int fno, char *buffer, unsigned count);
extern int my_write(int fno, const char *buffer, unsigned count);
extern int my_lseek(int fno, long offset, int origin);
extern int my_unlink(const char *path);
extern int my_rename(const char *old_name, const char *new_name);

main()
{
    FILE *fid;
    add_device("mydevice", _MSA, my_open, my_close, my_read, my_write, my_lseek,
               my_unlink, my_rename);

    fid = fopen("mydevice:test","w");
    fprintf(fid,"Hello, world\n");
    fclose(fid);
}
```
**close**

**Close File or Device For I/O**

**Syntax**

```c
#include <file.h>
int close(int file_descriptor);
```

**Description**

The close function closes the device or file associated with `file_descriptor`. The `file_descriptor` is the stream number assigned by the low-level routines that is associated with the opened device or file.

**Return Value**

The return value is one of the following:

- 0 if successful
- -1 if fails

---

**lseek**

**Set File Position Indicator**

**Syntax**

```c
#include <file.h>
off_t lseek(int file_descriptor, off_t offset, int origin);
```

**Description**

The lseek function sets the file position indicator for the given file to `origin + offset`. The file position indicator measures the position in characters from the beginning of the file.

- The `file_descriptor` is the stream number assigned by the low-level routines that the device-level driver must associate with the opened file or device.
- The `offset` indicates the relative offset from the `origin` in characters.
- The `origin` is used to indicate which of the base locations the `offset` is measured from. The `origin` must be a value returned by one of the following macros:
  - `SEEK_SET` (0x0000) Beginning of file
  - `SEEK_CUR` (0x0001) Current value of the file position indicator
  - `SEEK_END` (0x0002) End of file

**Return Value**

The return function is one of the following:

- # new value of the file-position indicator if successful
- EOF if fails
Open File or Device For I/O

Syntax

```
#include <file.h>

int open(const char *path, unsigned flags, int file_descriptor);
```

Description

The open function opens the device or file specified by `path` and prepares it for I/O.

- The `path` is the filename of the file to be opened, including path information.
- The `flags` are attributes that specify how the device or file is manipulated. The flags are specified using the following symbols:

```
O_RDONLY (0x0000) /* open for reading */
O_WRONLY (0x0001) /* open for writing */
O_RDWR (0x0002) /* open for read & write */
O_APPEND (0x0008) /* append on each write */
O_CREAT (0x0100) /* open with file create */
O_TRUNC (0x0200) /* open with truncation */
O_BINARY (0x8000) /* open in binary mode */
```

These parameters can be ignored in some cases, depending on how data is interpreted by the device. Note, however, that the high-level I/O calls look at how the file was opened in an fopen statement and prevent certain actions, depending on the open attributes.

- The `file_descriptor` is the stream number assigned by the low-level routines that is associated with the opened file or device.

The next available file_descriptor (in order from 3 to 20) is assigned to each new device opened. You can use the finddevice() function to return the device structure and use this pointer to search the _stream array for the same pointer. The file_descriptor number is the other member of the _stream array.

Return Value

The function returns one of the following values:

- `-1` if successful
- `-1` if fails
Read Characters From Buffer

Syntax

```c
#include <file.h>
int read(int file_descriptor, char *buffer, unsigned count);
```

Description

The `read` function reads the number of characters specified by `count` to the `buffer` from the device or file associated with `file_descriptor`.

- The `file_descriptor` is the stream number assigned by the low-level routines that is associated with the opened file or device.
- The `buffer` is the location of the buffer where the read characters are placed.
- The `count` is the number of characters to read from the device or file.

Return Value

The function returns one of the following values:

- 0 if EOF was encountered before the read was complete
- # number of characters read in every other instance
- -1 if fails

Rename File

Syntax

```c
#include <file.h>
int rename(const char *old_name, const char *new_name);
```

Description

The `rename` function changes the name of a file.

- The `old_name` is the current name of the file.
- The `new_name` is the new name for the file.

Return Value

The function returns one of the following values:

- 0 if the rename is successful
- Nonzero if fails
**unlink**

Delete File

**Syntax**

```c
#include <file.h>
int unlink(const char *path);
```

**Description**
The unlink function deletes the file specified by `path`.

The `path` is the filename of the file to be deleted, including path information.

**Return Value**
The function returns one of the following values:

- 0 if successful
- −1 if fails

---

**write**

Write Characters to Buffer

**Syntax**

```c
#include <file.h>
int write(int file_descriptor, const char *buffer, unsigned count);
```

**Description**
The write function writes the number of characters specified by `count` from the `buffer` to the device or file associated with `file_descriptor`.

- The `file_descriptor` is the stream number assigned by the low-level routines that is associated with the opened file or device.
- The `buffer` is the location of the buffer where the write characters are placed.
- The `count` is the number of characters to write to the device or file.

**Return Value**
The function returns one of the following values:

- # number of characters written if successful
- −1 if fails
7.3 Header Files

Each run-time-support function is declared in a header file. Each header file declares the following:

- A set of related functions (or macros)
- Any types that you need to use the functions
- Any macros that you need to use the functions

These are the header files that declare the ISO C run-time-support functions:

```
assert.h  inttypes.h  setjmp.h  stdio.h
ctype.h    iso646.h    stdarg.h  stdlib.h
errno.h    limits.h    stddef.h  string.h
float.h    math.h      stdint.h  time.h
```

In addition to the ISO C header files, the following C++ header files are included:

```
ccassert  climits     cstdio     new
ccctype   cmath       cstdlib    stdexcept
cerrno    csetjmp      cstring    typeinfo
cfloat    cstdioarg    ctime
cciso646  cstddef     exception
```

Furthermore, the following header files are included for the additional functions we provide:

```
c55x.h     cpy_tbl.h   file.h     gsm.h
```

To use a run-time-support function, you must first use the `#include` preprocessor directive to include the header file that declares the function. For example, the isdigit function is declared by the `ctype.h` header. Before you can use the isdigit function, you must first include `ctype.h`:

```
#include <ctype.h>
```

```
val = isdigit(num);
```

You can include headers in any order. You must, however, include a header before you reference any of the functions or objects that it declares.

Sections 7.3.1, *Diagnostic Messages (assert.h/cassert)*, on page 7-17 through 7.3.20, *Run-Time Type Information (typeinfo)*, on page 7-28 describe the header files that are included with the C/C++ compiler. Section 7.5, *Summary of Run-Time-Support Functions and Macros*, on page 7-39 lists the functions that these headers declare.
7.3.1 Diagnostic Messages (assert.h/cassert)

The assert.h/cassert header defines the assert macro, which inserts diagnostic failure messages into programs at run time. The assert macro tests a run time expression.

- If the expression is true (nonzero), the program continues running.

- If the expression is false, the macro outputs a message that contains the expression, the source file name, and the line number of the statement that contains the expression; then, the program terminates (using the abort function).

The assert.h/cassert header refers to another macro named NDEBUG (assert.h/cassert does not define NDEBUG). If you have defined NDEBUG as a macro name when you include assert.h/cassert, assert is turned off and does nothing. If NDEBUG is not defined, assert is enabled.

The assert.h header refers to another macro named NASSERT (assert.h does not define NASSERT). If you have defined NASSERT as a macro name when you include assert.h, assert acts like _nassert. The _nassert intrinsic generates no code and tells the optimizer that the expression declared with assert is true. This gives a hint to the optimizer as to what optimizations might be valid. If NASSERT is not defined, assert is enabled normally.

The assert function is listed in Table 7−3 (a) on page 7-30.

7.3.2 Character-Typing and Conversion (ctype.h/cctype)

The ctype.h/cctype header declares functions that test (type) and convert characters.

The character-typing functions test a character to determine whether it is a letter, a printing character, a hexadecimal digit, etc. These functions return a value of true (a nonzero value) or false (0). The character conversion functions convert characters to lower case, upper case, or ASCII, and return the converted character. Character-typing functions have names in the form isxxx (for example, isdigit). Character-conversion functions have names in the form toxxx (for example, toupper).
The `ctype.h`/`cctype` header also contains macro definitions that perform these same operations. The macros run faster than the corresponding functions. Use the function version if an argument passed to one of these macros has side effects. The typing macros expand to a lookup operation in an array of flags (this array is defined in `ctype.c`). The macros have the same name as the corresponding functions, but each macro is prefixed with an underscore (for example, `_isdigit_`).

The character typing and conversion functions are listed in Table 7–3 (b) on page 7-30.

### 7.3.3 Error Reporting (errno.h/cerrno)

The `errno.h`/`cerrno` header declares the `errno` variable. The `errno` variable declares errors in the math functions. Errors can occur in a math function if invalid parameter values are passed to the function or if the function returns a result that is outside the defined range for the type of the result. When this happens, a variable named `errno` is set to the value of one of the following macros:

- EDOM for domain errors (invalid parameter)
- ERANGE for range errors (invalid result)
- ENOENT for path errors (path does not exist)
- EFPOS for seek errors (file position error)

C code that calls a math function can read the value of `errno` to check for error conditions. The `errno` variable is declared in `errno.h/cerrno` and defined in `errno.c`.

C code that calls a math function can read the value of `errno` to check for error conditions. The `errno` variable is declared in `errno.h/cerrno` and defined in `errno.c/errno.cpp`.

### 7.3.4 Extended Addressing Functions (extaddr.h)

The `extaddr.h` header declares functions that support reading and writing of data in the full C55x address space. Extended memory addresses are represented by values of the integer type `FARPTR` (unsigned long).

The extended addressing functions are listed in Table 7–3 (c) on page 7-31.

### 7.3.5 Low-Level Input/Output Functions (file.h)

The `file.h` header declares the low-level I/O functions used to implement input and output operations. Section 7.2, *The C I/O Functions*, describes how to implement I/O for C55x.
7.3.6 Limits (float.h/cfloat and limits.h/climits)

The float.h/cfloat and limits.h/climits headers define macros that expand to useful limits and parameters of the processor’s numeric representations. Table 7–1 and Table 7–2 list these macros and their associated limits.

Table 7–1. Macros That Supply Integer Type Range Limits (limits.h)

<table>
<thead>

</table>

**Legend:**
- FLT_ applies to type float.
- DBL_ applies to type double.
- LDBL_ applies to type long double.

**Note:** The precision of some of the values in this table has been reduced for readability. See the float.h header file supplied with the compiler for the full precision carried by the processor.
7.3.7 Format Conversion of Integer Types (inttypes.h)

The stdint.h header declares sets of integer types of specified widths and defines corresponding sets of macros. The inttypes.h header contains stdint.h and also provides a set of integer types with definitions that are consistent across machines and independent of operating systems and other implementation idiosyncrasies. The inttypes.h header declares functions for manipulating greatest-width integers and converting numeric character strings to greatest-width integers.

Through typedef, inttypes.h defines integer types of various sizes. You are free to typedef integer types as standard C integer types or as the types provided in inttypes.h. Consistent use of the inttypes.h header greatly increases the portability of your program across platforms.

The header declares three types:

- The `imaxdiv_t` type, a structure type of the type of the value returned by the `imaxdiv` function
- The `intmax_t` type, an integer type large enough to represent any value of any signed integer type
- The `uintmax_t` type, an integer type large enough to represent any value of any unsigned integer type

The header declares several macros and functions:

- For each size type available on the architecture and provided in stdint.h, there are several fprintf and fscanf macros. For example, three fprintf macros for signed integers are `PRId32`, `PRIdLEAST32`, and `PRIdFAST32`. An example use of these macros is:

  ```c
  printf("The largest integer value is %020"PRIxMAX "\n", i);
  ```

- The `imaxabs` function that computes the absolute value of an integer of type `intmax_t`.

- The `strtoimax` and `strtoumax` functions, which are equivalent to the strtol, strtoll, strtoul, and strtoull functions. The initial portion of the string is converted to `intmax_t` and `uintmax_t`, respectively.

For detailed information on the inttypes.h header, see the ISO/IEC 9899:1999, *International Standard − Programming Languages − C (The C Standard).*
7.3.8 Alternative Spellings (iso646.h/ciso646)

The iso646.h/ciso646 header defines the following eleven macros that expand to the corresponding tokens:

<table>
<thead>
<tr>
<th>Macro</th>
<th>Token</th>
<th>Macro</th>
<th>Token</th>
</tr>
</thead>
<tbody>
<tr>
<td>and</td>
<td>&amp;&amp;</td>
<td>not_eq</td>
<td>!=</td>
</tr>
<tr>
<td>and_eq</td>
<td>&amp;=</td>
<td>or</td>
<td></td>
</tr>
<tr>
<td>bitand</td>
<td>&amp;</td>
<td>or_eq</td>
<td></td>
</tr>
<tr>
<td>bitor</td>
<td></td>
<td>xor</td>
<td>^</td>
</tr>
<tr>
<td>compl</td>
<td>~</td>
<td>xor_eq</td>
<td>^=</td>
</tr>
<tr>
<td>not</td>
<td>!</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

7.3.9 Floating-Point Math (math.h/cmath)

The math.h/cmath header defines several trigonometric, exponential, and hyperbolic math functions. These math functions expect double-precision floating-point arguments and return double-precision floating-point values.

The math.h/cmath header also defines one macro named HUGE_VAL; the math functions use this macro to represent out-of-range values. When a function produces a floating-point return value that is too large to be represented, it returns HUGE_VAL instead.

7.3.10 Nonlocal Jumps (setjmp.h/csetjmp)

The setjmp.h/csetjmp header defines a type, a macro, and a function for bypassing the normal function call and return discipline. These include:

- The array type jmp_buf, which is suitable for holding the information needed to restore a calling environment
- A macro setjmp, which saves its calling environment in its jmp_buf argument for later use by the longjmp function
- A function longjmp, which uses its jmp_buf argument to restore the program environment. The nonlocal jmp macro and function are listed in Table 7−3 (e) on page 7-32.
7.3.11 Variable Arguments (stdarg.h/cstdarg)

Some functions can have a variable number of arguments whose types can differ; such a function is called a variable-argument function. The stdarg.h/cstdarg header declares three macros and a type that help you to use variable-argument functions.

The three macros are va_start, va_arg, and va_end. These macros are used when the number and type of arguments may vary each time a function is called.

The type, va_list, is a pointer type that can hold information for va_start, va_end, and va_arg.

A variable-argument function can use the macros declared by stdarg.h to step through its argument list at run time when the function that is using the macro knows the number and types of arguments actually passed to it. You must ensure that a call to a variable-argument function has visibility to a prototype for the function in order for the arguments to be handled correctly. The variable argument functions are listed in Table 7–3 (f) page 7-32.

7.3.12 Standard Definitions (stddef.h/cstddef)

The stddef.h/cstddef header defines two types and two macros. The types include:

- The _ptrdiff_t type, a signed integer type that is the data type resulting from the subtraction of two pointers
- The _size_t type, an unsigned integer type that is the data type of the _sizeof operator.

The macros include:

- The NULL macro, which expands to a null pointer constant (0)
- The offsetof(type, identifier) macro, which expands to an integer that has type _size_t. The result is the value of an offset in bytes to a structure member (identifier) from the beginning of its structure (type).

These types and macros are used by several of the run-time-support functions.
**7.3.13 Integer Types (stdint.h)**

The stdint.h header declares sets of integer types of specified widths and defines corresponding sets of macros. It also defines macros that specify limits of integer types that correspond to types defined in other standard headers. Types are defined in these categories:

- Integer types with certain exact widths of the signed form `intN_t` and of the unsigned form `uintN_t`
- Integer types with at least certain specified widths of the signed form `int_leastN_t` and of the unsigned form `uint_leastN_t`
- Fastest integer types with at least certain specified widths of the signed form `int_fastN_t` and of the unsigned form `uint_fastN_t`
- Signed, `intptr_t`, and unsigned, `uintptr_t`, integer types large enough to hold a pointer value
- Signed, `intmax_t`, and unsigned, `uintmax_t`, integer types large enough to represent any value of any integer type

For each signed type provided by stdint.h there is a macro that specifies the minimum or maximum limit. Each macro name corresponds to a similar type name described above.

The `INTN_C(value)` macro expands to a signed integer constant with the specified value and type `int_leastN_t`. The unsigned `UINTN_C(value)` macro expands to an unsigned integer constant with the specified value and type `uint_leastN_t`.

This example shows a macro defined in stdint.h that uses the smallest integer that can hold at least 16 bits:

```c
typedef uint_least_16 id_number;
extern id_number lookup_user(char *uname);
```

For detailed information on the stdint.h header, see the ISO/IEC 9899:1999, *International Standard – Programming Languages – C (The C Standard)*.
7.3.14 Input/Output Functions (stdio.h/cstdio)

The stdio.h/cstdio header defines seven macros, two types, a structure, and a number of functions. The types and structure include:

- The `size_t` type, an unsigned integer type that is the data type of the `sizeof` operator. The original declaration is in stddef.h/cstddef.
- The `fpos_t` type, an unsigned long type that can uniquely specify every position within a file.
- The `FILE` structure that records all the information necessary to control a stream.

The macros include:

- The `NULL` macro, which expands to a null pointer constant(0). The original declaration is in stddef.h. It will not be redefined if it has already been defined.
- The `BUFSIZ` macro, which expands to the size of the buffer that `setbuf()` uses.
- The `EOF` macro, which is the end-of-file marker.
- The `FOPEN_MAX` macro, which expands to the largest number of files that can be open at one time.
- The `FILENAME_MAX` macro, which expands to the length of the longest file name in characters.
- The `L_tmpnam` macro, which expands to the longest filename string that `tmpnam()` can generate.
- `SEEK_CUR`, `SEEK_SET`, and `SEEK_END`, macros that expand to indicate the position (current, start-of-file, or end-of-file, respectively) in a file.
- `TMP_MAX`, a macro that expands to the maximum number of unique filenames that `tmpnam()` can generate.
- `stderr`, `stdin`, `stdout`, which are pointers to the standard error, input, and output files, respectively.

The input/output functions are listed in Table 7–3 (g) on page 7-33.
7.3.15 General Utilities (stdlib.h/cstdlib)

The stdlib.h/cstdlib header declares several functions, one macro, and two types. The types include:

- The `div_t` structure type that is the type of the value returned by the `div` function
- The `ldiv_t` structure type that is the type of the value returned by the `ldiv` function

The macro, `RAND_MAX`, is the maximum random number the rand function will return.

The header also declares many of the common library functions:

- String conversion functions that convert strings to numeric representations
- Searching and sorting functions that allow you to search and sort arrays
- Sequence-generation functions that allow you to generate a pseudorandom sequence and allow you to choose a starting point for a sequence
- Program-exit functions that allow your program to terminate normally or abnormally
- Integer arithmetic that is not provided as a standard part of the C language

The general utility functions are listed in Table 7–3 (h) on page 7-35.
7.3.16 String Functions (string.h/cstring)

The string.h/cstring header declares standard functions that allow you to perform the following tasks with character arrays (strings):

- Move or copy entire strings or portions of strings
- Concatenate strings
- Compare strings
- Search strings for characters or other strings
- Find the length of a string

In C, all character strings are terminated with a 0 (null) character. The string functions named `strxxx` all operate according to this convention. Additional functions that are also declared in string.h/cstring allow you to perform corresponding operations on arbitrary sequences of bytes (data objects) where a 0 value does not terminate the object. These functions have names such as `memxxx`.

When you use functions that move or copy strings, be sure that the destination is large enough to contain the result. The string functions are listed in Table 7–3 (i) on page 7-37.

7.3.17 Time Functions (time.h/ctime)

The time.h/ctime header declares one macro, several types, and functions that manipulate dates and times. Times are represented in two ways:

- As an arithmetic value of type `time_t`. When expressed in this way, a time is represented as a number of seconds since 12:00 AM January 1, 1900. The `time_t` type is a synonym for the type unsigned long.
- As a structure of type `struct_tm`. This structure contains members for expressing time as a combination of years, months, days, hours, minutes, and seconds. A time represented like this is called broken-down time. The structure has the following members:

```c
int tm_sec; /* seconds after the minute (0−59) */
int tm_min; /* minutes after the hour (0−59) */
int tm_hour; /* hours after midnight (0−23) */
int tm_mday; /* day of the month (1−31) */
int tm_mon; /* months since January (0−11) */
int tm_year; /* years since 1900 */
int tm_wday; /* days since Saturday (0−6) */
int tm_yday; /* days since January 1 (0−365) */
int tm_isdst; /* daylight savings time flag */
```

A time, whether represented as a `time_t` or a `struct_tm`, can be expressed from different points of reference:

- Calendar time represents the current Gregorian date and time.
- Local time is the calendar time expressed for a specific time zone.
The time functions and macros are listed in Table 7−3 (j) on page 7-38.

Local time can be adjusted for daylight savings time. Obviously, local time depends on the time zone. The time.h/ctime header declares a structure type called tmzone and a variable of this type called _tz. You can change the time zone by modifying this structure, either at run time or by editing tmzone.c and changing the initialization. The default time zone is Central Standard Time, U.S.A.

The basis for all the functions in time.h are two system functions: clock and time. Time provides the current time (in time_t format), and clock provides the system time (in arbitrary units). The value returned by clock can be divided by the macro CLOCKS_PER_SEC to convert it to seconds. Since these functions and the CLOCKS_PER_SEC macro are system specific, only stubs are provided in the library. To use the other time functions, you must supply custom versions of these functions.

**Note: Writing Your Own Clock Function**

A host-specific clock function can be written. You must also define the CLOCKS_PER_SEC macro according to the units of your clock so that the value returned by clock()—number of clock ticks—can be divided by CLOCKS_PER_SEC to produce a value in seconds.

### 7.3.18 Exception Handling (exception and stdexcept)

Exception handling is not supported. The exception and stdexcept include files, which are for C++ only, are empty.

### 7.3.19 Dynamic Memory Management (new)

The new header, which is for C++ only, defines functions for new, new[], delete, delete[], and their placement versions.

The type new_handler and the function set_new_handler() are also provided to support error recovery during memory allocation.

### 7.3.20 Run-Time Type Information (typeinfo)

The typeinfo header, which is for C++ only, defines the type_info structure, which is used to represent C++ type information at run time.
Table 7–3 summarizes the run-time-support header files (in alphabetical order) provided with the TMS320C55x ISO C/C++ compiler. Most of the functions described are per the ISO standard and behave exactly as described in the standard.

The functions and macros listed in Table 7–3 are described in detail in section 7.5, *Description of Run-Time-Support Functions and Macros* on page 7-39. For a complete description of a function or macro, see the indicated page.

A superscripted number is used in the following descriptions to show exponents. For example, \( x^y \) is the equivalent of \( x \) to the power \( y \).
## Table 7-3. Summary of Run-Time-Support Functions and Macros

(a) Error message macro (assert.h/cassert)

<table>

<td>Returns $e^x$</td>
<td>7-50</td>
</tr>
<tr>
<td>double fabs(double x);</td>
<td>Returns the absolute value of x</td>
<td>7-50</td>
</tr>
<tr>
<td>double floor(double x);</td>
<td>Returns the largest integer ≤ x; expands inline if −x is used</td>
<td>7-55</td>
</tr>
<tr>
<td>double fmod(double x, double y);</td>
<td>Returns the exact floating-point remainder of x/y</td>
<td>7-55</td>
</tr>
<tr>
<td>double frexp(double value, int *exp);</td>
<td>Returns f and exp such that $0.5 \leq</td>
<td>f</td>
</tr>
<tr>
<td>double ldexp(double x, int exp);</td>
<td>Returns $x \times 2^{\text{exp}}$</td>
<td>7-64</td>
</tr>
</tbody>
</table>
### Summary of Run-Time-Support Functions and Macros

#### (d) Floating-point math functions (math.h/cmath) (Continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>double log(double x);</td>
<td>Returns the natural logarithm of x</td>
<td>7-65</td>
</tr>
<tr>
<td>double log10(double x);</td>
<td>Returns the base-10 logarithm of x</td>
<td>7-66</td>
</tr>
<tr>
<td>double modf(double value, double *ip);</td>
<td>Breaks value into a signed integer and a signed fraction</td>
<td>7-71</td>
</tr>
<tr>
<td>double pow(double x, double y);</td>
<td>Returns ( x^y )</td>
<td>7-72</td>
</tr>
<tr>
<td>double sin(double x);</td>
<td>Returns the sine of x</td>
<td>7-80</td>
</tr>
<tr>
<td>double sinh(double x);</td>
<td>Returns the hyperbolic sine of x</td>
<td>7-80</td>
</tr>
<tr>
<td>double sqrt(double x);</td>
<td>Returns the nonnegative square root of x</td>
<td>7-81</td>
</tr>
<tr>
<td>double tan(double x);</td>
<td>Returns the tangent of x</td>
<td>7-94</td>
</tr>
<tr>
<td>double tanh(double x);</td>
<td>Returns the hyperbolic tangent of x</td>
<td>7-95</td>
</tr>
</tbody>
</table>

#### (e) Nonlocal jumps macro and function (setjmp.h/csetjmp)

<table>
<thead>
<tr>
<th>Function or Macro</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>int setjmp(jmp_buf env);</td>
<td>Saves calling environment for use by longjmp; this is a macro</td>
<td>7-78</td>
</tr>
<tr>
<td>void longjmp(jmp_buf env, int _val);</td>
<td>Uses jmp_buf argument to restore a previously saved environment</td>
<td>7-78</td>
</tr>
</tbody>
</table>

#### (f) Variable argument macros (stdarg.h/cstdarg)

<table>
<thead>
<tr>
<th>Macro</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>type va_arg(va_list, type);</td>
<td>Accesses the next argument of type type in a variable-argument list</td>
<td>7-98</td>
</tr>
<tr>
<td>void va_end(va_list);</td>
<td>Resets the calling mechanism after using va_arg</td>
<td>7-98</td>
</tr>
<tr>
<td>void va_start(va_list, parmN);</td>
<td>Initializes ap to point to the first operand in the variable-argument list</td>
<td>7-98</td>
</tr>
</tbody>
</table>
### Summary of Run-Time-Support Functions and Macros

#### (g) C I/O functions (stdio.h/cstdio)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>int add_device()</td>
<td>Adds a device record to the device table</td>
<td>7-10</td>
</tr>
<tr>
<td>void clearerr()</td>
<td>Clears the EOF and error indicators for the stream that _fp points to</td>
<td>7-46</td>
</tr>
<tr>
<td>int fclose()</td>
<td>Flushes the stream that _fp points to and closes the file associated with that stream</td>
<td>7-53</td>
</tr>
<tr>
<td>int feof()</td>
<td>Tests the EOF indicator for the stream that _fp points to</td>
<td>7-53</td>
</tr>
<tr>
<td>int ferror()</td>
<td>Tests the error indicator for the stream that _fp points to</td>
<td>7-53</td>
</tr>
<tr>
<td>int fflush()</td>
<td>Flushes the I/O buffer for the stream that _fp points to</td>
<td>7-54</td>
</tr>
<tr>
<td>int fgetc()</td>
<td>Reads the next character in the stream that _fp points to</td>
<td>7-54</td>
</tr>
<tr>
<td>int fgetpos()</td>
<td>Stores the object that pos points to to the current value of the file position indicator for the stream that _fp points to</td>
<td>7-54</td>
</tr>
<tr>
<td>char *fgets()</td>
<td>Reads the next _size minus 1 characters from the stream that _fp points to into array _ptr</td>
<td>7-55</td>
</tr>
<tr>
<td>FILE *fopen()</td>
<td>Opens the file that _fname points to using the stream that _fp points to; _mode points to a string describing how to open the file</td>
<td>7-56</td>
</tr>
<tr>
<td>int fscanf()</td>
<td>Reads formatted input from the stream that _fp points to</td>
<td>7-59</td>
</tr>
<tr>
<td>size_t fread()</td>
<td>Reads from the stream pointed to by _fp and stores the input to the array pointed to by _ptr</td>
<td>7-57</td>
</tr>
<tr>
<td>FILE *freopen()</td>
<td>Opens the file that _fname points to using the stream that _fp points to; _mode points to a string describing how to open the file</td>
<td>7-58</td>
</tr>
<tr>
<td>int fgets()</td>
<td>razier the next _size minus 1 characters from the stream that _fp points to into array _ptr</td>
<td>7-55</td>
</tr>
</tbody>
</table>
### Summary of Run-Time-Support Functions and Macros

#### (g) C I/O functions (stdio.h/cstdio) (Continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>int <code>fseek</code>(register FILE *fp, long offset, int _ptname);</td>
<td>Sets the file position indicator for the stream that fp points to</td>
<td>7-59</td>
</tr>
<tr>
<td>int <code>fsetpos</code>(FILE *fp, const fpos_t *pos);</td>
<td>Sets the file position indicator for the stream that fp points to pos. The pointer pos must be a value from fgetpos() on the same stream.</td>
<td>7-60</td>
</tr>
<tr>
<td>long <code>ftell</code>(FILE *fp);</td>
<td>Obtains the current value of the file position indicator for the stream that fp points to</td>
<td>7-60</td>
</tr>
<tr>
<td>size_t <code>fwrite</code>(const void *ptr, size_t size, size_t count, register FILE *fp);</td>
<td>Writes a block of data from the memory pointed to by ptr to the stream that fp points to</td>
<td>7-60</td>
</tr>
<tr>
<td>int <code>getc</code>(FILE *fp);</td>
<td>Reads the next character in the stream that fp points to</td>
<td>7-61</td>
</tr>
<tr>
<td>int <code>getchar</code>(void);</td>
<td>A macro that calls fgetc() and supplies stdin as the argument</td>
<td>7-61</td>
</tr>
<tr>
<td>char *<code>gets</code>(char *ptr);</td>
<td>Performs the same function as fgets() using stdin as the input stream</td>
<td>7-62</td>
</tr>
<tr>
<td>void <code>perror</code>(const char *s);</td>
<td>Maps the error number in s to a string and prints the error message</td>
<td>7-72</td>
</tr>
<tr>
<td>int <code>printf</code>(const char *format, ...);</td>
<td>Performs the same function as fprintf but uses stdout as its output stream</td>
<td>7-72</td>
</tr>
<tr>
<td>int <code>putc</code>(int x, FILE *fp);</td>
<td>A macro that performs like fputc()</td>
<td>7-73</td>
</tr>
<tr>
<td>int <code>putchar</code>(int x);</td>
<td>A macro that calls fputc() and uses stdout as the output stream</td>
<td>7-73</td>
</tr>
<tr>
<td>int <code>puts</code>(const char *ptr);</td>
<td>Writes the string pointed to by ptr to stdout</td>
<td>7-73</td>
</tr>
<tr>
<td>int <code>remove</code>(const char *file);</td>
<td>Causes the file with the name pointed to by file to be no longer available by that name</td>
<td>7-76</td>
</tr>
<tr>
<td>int <code>rename</code>(const char *old_name, const char *new_name);</td>
<td>Causes the file with the name pointed to by old_name to be known by the name pointed to by new_name</td>
<td>7-76</td>
</tr>
<tr>
<td>void <code>rewind</code>(register FILE *fp);</td>
<td>Sets the file position indicator for the stream pointed to by fp to the beginning of the file</td>
<td>7-77</td>
</tr>
<tr>
<td>int <code>scanf</code>(const char *fmt, ...);</td>
<td>Performs the same function as fscanf() but reads input from stdin</td>
<td>7-77</td>
</tr>
<tr>
<td>void <code>setbuf</code>(register FILE *fp, char *buf);</td>
<td>Returns no value. setbuf() is a restricted version of setvbuf() and defines and associates a buffer with a stream</td>
<td>7-77</td>
</tr>
</tbody>
</table>
(g) C I/O functions (stdio.h/cstdio) (Continued)

<table>

<tr>
<td><code>ldiv_t ldiv(register long numer, register long denom);</code></td>
<td>Divides numerator by denominator</td>
<td>7-49</td>
</tr>
<tr>
<td><code>int ltoa(long val, char *buffer);</code></td>
<td>Converts val to the equivalent string</td>
<td>7-66</td>
</tr>
<tr>
<td><code>void *malloc(size_t size);</code></td>
<td>Allocates memory for an object of size bytes</td>
<td>7-67</td>
</tr>
<tr>
<td><code>void minit(void);</code></td>
<td>Resets all the memory previously allocated by malloc, calloc, or realloc</td>
<td>7-71</td>
</tr>
<tr>
<td><code>void qsort(void *base, size_t nmemb, size_t size, int (*compar)());</code></td>
<td>Sorts an array of nmemb members; base points to the first member of the unsorted array, and size specifies the size of each member</td>
<td>7-74</td>
</tr>
<tr>
<td><code>int rand(void);</code></td>
<td>Returns a sequence of pseudorandom integers in the range 0 to RAND_MAX</td>
<td>7-75</td>
</tr>
<tr>
<td><code>void *realloc(void *packet, size_t size);</code></td>
<td>Changes the size of an allocated memory space</td>
<td>7-75</td>
</tr>
<tr>
<td><code>void srand(unsigned int seed);</code></td>
<td>Resets the random number generator</td>
<td>7-75</td>
</tr>
<tr>
<td><code>double strtod(const char *st, char **endptr);</code></td>
<td>Converts a string to a floating-point value</td>
<td>7-92</td>
</tr>
<tr>
<td><code>long strtol(const char *st, char **endptr, int base);</code></td>
<td>Converts a string to a long integer</td>
<td>7-92</td>
</tr>
<tr>
<td><code>unsigned long strtoul(const char *st, char **endptr, int base);</code></td>
<td>Converts a string to an unsigned long integer</td>
<td>7-92</td>
</tr>
</tbody>
</table>
### Summary of Run-Time-Support Functions and Macros

#### (i) String functions (string.h/cstring)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>memchr(void *cs, int c, size_t n);</code></td>
<td>Finds the first occurrence of <code>c</code> in the first <code>n</code> characters of <code>cs</code>; expands inline if <code>−x</code> is used</td>
<td>7-67</td>
</tr>
<tr>
<td><code>memcmp(const void *cs, const void *ct, size_t n);</code></td>
<td>Compares the first <code>n</code> characters of <code>cs</code> to <code>ct</code>; expands inline if <code>−x</code> is used</td>
<td>7-68</td>
</tr>
<tr>
<td><code>memcpy(void *s1, const void *s2, size_t n);</code></td>
<td>Copies <code>n</code> characters from <code>s1</code> to <code>s2</code></td>
<td>7-68</td>
</tr>
<tr>
<td><code>memmove(void *s1, const void *s2, size_t n);</code></td>
<td>Moves <code>n</code> characters from <code>s1</code> to <code>s2</code></td>
<td>7-69</td>
</tr>
<tr>
<td><code>memset(void *mem, int ch, size_t length);</code></td>
<td>Copies the value of <code>ch</code> into the first <code>length</code> characters of <code>mem</code>; expands inline if <code>−x</code> is used</td>
<td>7-69</td>
</tr>
<tr>
<td><code>strcat(char *string1, const char *string2);</code></td>
<td>Appends <code>string2</code> to the end of <code>string1</code></td>
<td>7-82</td>
</tr>
<tr>
<td><code>strchr(const char *string, int c);</code></td>
<td>Finds the first occurrence of character <code>c</code> in <code>s</code>; expands inline if <code>−x</code> is used</td>
<td>7-83</td>
</tr>
<tr>
<td><code>strcmp(register const char *string1, register const char *string2);</code></td>
<td>Compares strings and returns one of the following values: <code>&lt;0</code> if <code>string1</code> is less than <code>string2</code>; <code>0</code> if <code>string1</code> is equal to <code>string2</code>; <code>&gt;0</code> if <code>string1</code> is greater than <code>string2</code>. Expands inline if <code>−x</code> is used</td>
<td>7-84</td>
</tr>
<tr>
<td><code>strcoll(const char *string1, const char *string2);</code></td>
<td>Compares strings and returns one of the following values: <code>&lt;0</code> if <code>string1</code> is less than <code>string2</code>; <code>0</code> if <code>string1</code> is equal to <code>string2</code>; <code>&gt;0</code> if <code>string1</code> is greater than <code>string2</code>.</td>
<td>7-84</td>
</tr>
<tr>
<td><code>strcpy(register char *dest, register const char *src);</code></td>
<td>Copies string <code>src</code> into <code>dest</code>; expands inline if <code>−x</code> is used</td>
<td>7-85</td>
</tr>
<tr>
<td><code>strcspn(const char *string, const char *chs);</code></td>
<td>Returns the length of the initial segment of <code>string</code> that is made up entirely of characters that are not in <code>chs</code></td>
<td>7-85</td>
</tr>
<tr>
<td><code>strerror(int errno);</code></td>
<td>Maps the error number in <code>errno</code> to an error message string</td>
<td>7-86</td>
</tr>
<tr>
<td><code>strlen(const char *string);</code></td>
<td>Returns the length of a string</td>
<td>7-87</td>
</tr>
<tr>
<td><code>strcat(char *dest, const char *src, register size_t n);</code></td>
<td>Appends up to <code>n</code> characters from <code>src</code> to <code>dest</code></td>
<td>7-88</td>
</tr>
<tr>
<td><code>strncmp(const char *string1, const char *string2, size_t n);</code></td>
<td>Compares up to <code>n</code> characters in two strings; expands inline if <code>−x</code> is used</td>
<td>7-89</td>
</tr>
<tr>
<td><code>strncpy(register char *dest, register const char *src, register size_t n);</code></td>
<td>Copies up to <code>n</code> characters from <code>src</code> to <code>dest</code>; expands inline if <code>−x</code> is used</td>
<td>7-89</td>
</tr>
</tbody>
</table>
Summary of Run-Time-Support Functions and Macros

(i) String functions (string.h/cstring) (Continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>char *strpbrk(const char *string, const char *chs);</td>
<td>Locates the first occurrence in string of any character from chs</td>
<td>7-90</td>

<td>clock_t clock(void);</td>
<td>Determines the processor time used</td>
<td>7-46</td>
</tr>
<tr>
<td>char *ctime(const time_t *timer);</td>
<td>Converts calendar time to local time</td>
<td>7-48</td>
</tr>
<tr>
<td>double difftime(time_t time1, time_t time0);</td>
<td>Returns the difference between two calendar times</td>
<td>7-48</td>
</tr>
<tr>
<td>struct tm *gmtime(const time_t *timer);</td>
<td>Converts local time to Greenwich Mean Time</td>
<td>7-62</td>
</tr>
<tr>
<td>struct tm *localtime(const time_t *timer);</td>
<td>Converts time_t value to broken down time</td>
<td>7-65</td>
</tr>
<tr>
<td>time_t mktime(register struct tm *tptr);</td>
<td>Converts broken down time to a time_t value</td>
<td>7-69</td>
</tr>
<tr>
<td>size_t strftime(char *out, size_t maxsize, const char *format, const struct tm *time);</td>
<td>Formats a time into a character string</td>
<td>7-86</td>
</tr>
<tr>
<td>time_t time(time_t *timer);</td>
<td>Returns the current calendar time</td>
<td>7-95</td>
</tr>
</tbody>
</table>
7.5 Description of Run-Time-Support Functions and Macros

This section describes the run-time-support functions and macros. For each function or macro, the syntax is given in both C and C++. Because the functions and macros originated from C header files; however, program examples are shown in C code only. The same program in C++ code would differ in that the types and functions declared in the header file are introduced into the std namespace.

**Abort**

**Syntax**

```c
#include <stdlib.h>
void abort(void);
```

**Syntax for C++**

```c++
#include <cstdlib>
void std::abort(void);
```

**Defined in**

exit.c in rts.src

**Description**

The abort function terminates the program.

**Example**

```c
if (error_detected)
    abort();
```

**Absolute Value**

**Syntax**

```c
#include <stdlib.h>
int abs(int j);
long labs(long i);
long long llabs (long long k);
```

**Syntax for C++**

```c++
#include <cstdlib>
int std::abs(int j);
long std::labs(long i);
long long std::llabs(long long k);
```

**Defined in**

abs.c in rts.src

**Description**

The C/C++ compiler supports two functions that return the absolute value of an integer:

- The abs function returns the absolute value of an integer j.
- The labs function returns the absolute value of a long integer i.
- The llabs function returns the absolute value of a long integer k.
acos

**Arc Cosine**

**Syntax**
```
#include <math.h>

double acos(double x);
```

**Syntax for C++**
```
#include <cmath>

double std::acos(double x);
```

**Defined in**
acos.c in rts.src

**Description**
The acos function returns the arc cosine of a floating-point argument x, which must be in the range \([-1,1]\). The return value is an angle in the range \([0,\pi]\) radians.

**Example**
```
double realval, radians;

realval = 1.0;
radians = acos(realval);
return (radians); /* acos return \(\pi/2\) */
```

asctime

**Internal Time to String**

**Syntax**
```
#include <time.h>

char *asctime(const struct tm *timeptr);
```

**Syntax for C++**
```
#include <ctime>

char *std::asctime(const struct tm *timeptr);
```

**Defined in**
asctime.c in rts.src

**Description**
The asctime function converts a broken-down time into a string with the following form:
```
Mon Jan 11 11:18:36 1988
```
The function returns a pointer to the converted string.

For more information about the functions and types that the `time.h` header declares and defines, see section 7.3.17, *Time Functions (time.h)*, on page 7-27.
### asin

#### Arc Sine

**Syntax**

```c
#include <math.h>
double asin(double x);
```

**Syntax for C++**

```c
#include <cmath>
double std::asin(double x);
```

**Defined in**

asin.c in rts.src

**Description**

The `asin` function returns the arc sine of a floating-point argument `x`, which must be in the range \([-1, 1]\). The return value is an angle in the range \([-\pi/2, \pi/2]\) radians.

**Example**

```c
double realval, radians;
realval = 1.0;
radians = asin(realval); /* asin returns \pi/2 */
```

### assert

#### Insert Diagnostic Information Macro

**Syntax**

```c
#include <assert.h>
void assert(int expr);
```

**Syntax for C++**

```c
#include <cassert>
void std::assert(int expr);
```

**Defined in**

assert.h/cassert as macro

**Description**

The `assert` macro tests an expression; depending upon the value of the expression, assert either issues a message and aborts execution or continues execution. This macro is useful for debugging.

- If expr is false, the assert macro writes information about the call that failed to the standard output and then aborts execution.
- If expr is true, the assert macro does nothing.

The header file that declares the assert macro refers to another macro, NDEBUG. If you have defined NDEBUG as a macro name when the assert.h header is included in the source file, the assert macro is defined as:

```c
#define assert(ignore)
```

**Example**

In this example, an integer `i` is divided by another integer `j`. Since dividing by 0 is an illegal operation, the example uses the assert macro to test `j` before the division. If `j` = 0, assert issues a message and aborts the program.

```c
int i, j;
assert(j);
q = i/j;
```
atan

**Polar Arc Tangent**

**Syntax**
```c
#include <math.h>

double atan(double x);
```

**Syntax for C++**
```cpp
#include <cmath>

double std::atan(double x);
```

**Defined in**
atan.c in rts.src

**Description**
The atan function returns the arc tangent of a floating-point argument x. The return value is an angle in the range \([-\pi/2, \pi/2]\) radians.

**Example**
```c
double realval, radians;

realval = 0.0;
radians = atan(realval);  /* return value = 0 */
```

atan2

**Cartesian Arc Tangent**

**Syntax**
```c
#include <math.h>

double atan2(double y, double x);
```

**Syntax for C++**
```cpp
#include <cmath>

double std::atan2(double y, double x);
```

**Defined in**
atan2.c in rts.src

**Description**
The atan2 function returns the inverse tangent of \(y/x\). The function uses the signs of the arguments to determine the quadrant of the return value. Both arguments cannot be 0. The return value is an angle in the range \([-\pi, \pi]\) radians.

**Example**
```c
double rvalu, rvalv;
double radians;

rvalu = 0.0;
rvalv = 1.0;
radians = atan2(rvalu, rvalv);  /* return value = 0 */
```
**atexit**

*Register Function Called by Exit ()*

**Syntax**

```c
#include <stdlib.h>
int atexit(void (*fun)(void));
```

**Syntax for C++**

```c++
#include <cstdlib>
int std::atexit(void (*fun)(void));
```

**Defined in**

`exit.c` in `rts.src`

**Description**

The `atexit` function registers the function that is pointed to by `fun`, to be called without arguments at normal program termination. Up to 32 functions can be registered.

When the program exits through a call to the `exit` function, the functions that were registered are called, without arguments, in reverse order of their registration.

---

**atof/atoi/atol**

*String to Number*

**Syntax**

```c
#include <stdlib.h>
double atof(const char *st);
int atoi(const char *st);
long atol(const char *st);
```

**Syntax for C++**

```c++
#include <cstdlib>
double std::atof(const char *st);
int std::atoi(const char *st);
long std::atol(const char *st);
```

**Defined in**

`atof.c`, `atoi.c`, and `atol.c` in `rts.src`

**Description**

Three functions convert strings to numeric representations:

- The `atof` function converts a string into a floating-point value. Argument `st` points to the string. The string must have the following format:
  
  `[space] [sign] digits [digits] [e|E [sign] integer]`

- The `atoi` function converts a string into an integer. Argument `st` points to the string; the string must have the following format:
  
  `[space] [sign] digits`

- The `atol` function converts a string into a long integer. Argument `st` points to the string. The string must have the following format:
  
  `[space] [sign] digits`
The space is indicated by a space (character), a horizontal or vertical tab, a carriage return, a form feed, or a new line. Following the space is an optional sign, and the digits that represent the integer portion of the number. The fractional part of the number follows, then the exponent, including an optional sign.

The first character that cannot be part of the number terminates the string.

The functions do not handle any overflow resulting from the conversion.

---

**Array Search**

**Syntax**

```c
#include <stdlib.h>

void *bsearch(const void *key, register const void *base,
    size_t nmemb, size_t size,
    int (*compar)(const void *, const void *));
```

**Syntax for C++**

```c
#include <cstdlib>

void *std::bsearch(const void *key, register const void *base,
    size_t nmemb, size_t size,
    int (*compar)(const void *, const void *));
```

**Defined in**

bsearch.c in rts.src

**Description**

The bsearch function searches through an array of nmemb objects for a member that matches the object that key points to. Argument base points to the first member in the array; size specifies the size (in bytes) of each member.

The contents of the array must be in ascending order. If a match is found, the function returns a pointer to the matching member of the array; if no match is found, the function returns a null pointer (0).

Argument compar points to a function that compares key to the array elements. The comparison function should be declared as:

```c
int cmp(const void *ptr1, const void *ptr2)
```

The cmp function compares the objects that ptr1 and ptr2 point to and returns one of the following values:

- `< 0` if *ptr1 is less than *ptr2
- `0` if *ptr1 is equal to *ptr2
- `> 0` if *ptr1 is greater than *ptr2
### calloc

#### Allocate and Clear Memory

**Syntax**

```c
#include <stdlib.h>

void *calloc(size_t num, size_t size);
```

**Syntax for C++**

```cpp
#include <cstdlib>

void *std::calloc(size_t num, size_t size);
```

**Defined in**

memory.c in rts.src

**Description**

The calloc function allocates size bytes (size is an unsigned integer or size_t) for each of num objects and returns a pointer to the space. The function initializes the allocated memory to all 0s. If it cannot allocate the memory (that is, if it runs out of memory), it returns a null pointer (0).

The memory that calloc uses is in a special memory pool or heap. The constant `__SYSMEM_SIZE` defines the size of the heap as 2000 bytes. You can change this amount at link time by invoking the linker with the `−heap` option and specifying the desired size of the heap (in bytes) directly after the option. For more information, see section 6.1.6, *Dynamic Memory Allocation*, on page 6-7.

**Example**

This example uses the calloc routine to allocate and clear 20 bytes.

```c
prt = calloc (10,2) ;  /*Allocate and clear 20 bytes */
```

### ceil

#### Ceiling

**Syntax**

```c
#include <math.h>

double ceil(double x);
```

**Syntax for C++**

```cpp
#include <cmath>

double std::ceil(double x);
```

**Defined in**

ceil.c in rts.src

**Description**

The ceil function returns a floating-point number that represents the smallest integer greater than or equal to x.

**Example**

```c
extern double ceil();

double answer;

answer = ceil(3.1415);  /* answer = 4.0 */
answer = ceil(-3.5);     /* answer = -3.0 */
```
clearerr

**clearerr**  
*Clear EOF and Error Indicators*

**Syntax**

```c
#include <stdio.h>

void clearerr(FILE *fp);
```

**Syntax for C++**

```c
#include <cstdio>

void std::clearerr(FILE *fp);
```

**Defined in**
clearerr in rts/src

**Description**
The clearerr function clears the EOF and error indicators for the stream that \_fp points to.

clock

**clock**  
*Processor Time*

**Syntax**

```c
#include <time.h>

clock_t clock(void);
```

**Syntax for C++**

```c
#include <ctime>

clock_t std::clock(void);
```

**Defined in**
clock.c in rts/src

**Description**
The clock function determines the amount of processor time used. It returns an approximation of the processor time used by a program since the program began running. The time in seconds is the return value divided by the value of the macro CLOCKS_PER_SEC.

If the processor time is not available or cannot be represented, the clock function returns the value of \((\text{clock}_t - 1)\).

**Note: Writing Your Own Clock Function**
The clock function is host-system specific, so you must write your own clock function. You must also define the CLOCKS_PER_SEC macro according to the units of your clock so that the value returned by `clock()` — number of clock ticks — can be divided by CLOCKS_PER_SEC to produce a value in seconds.
**Cos**  

**Cosine**

**Syntax**

```c
#include <math.h>

double cos(double x);
```

**Syntax for C++**

```c
#include <cmath>

double std::cos(double x);
```

**Defined in**

cos.c in rts.src

**Description**

The cos function returns the cosine of a floating-point number x. The angle x is expressed in radians. An argument with a large magnitude can produce a result with little or no significance.

**Example**

```c
double radians, cval; /* cos returns cval */
radians = 3.1415927;
cval = cos(radians); /* return value = -1.0 */
```

---

**cosh**  

**Hyperbolic Cosine**

**Syntax**

```c
#include <math.h>

double cosh(double x);
```

**Syntax for C++**

```c
#include <cmath>

double std::cosh(double x);
```

**Defined in**

cosh.c in rts.src

**Description**

The cosh function returns the hyperbolic cosine of a floating-point number x. A range error occurs if the magnitude of the argument is too large.

**Example**

```c
double x, y;
x = 0.0;
y = cosh(x); /* return value = 1.0 */
```
ctime

**Calendar Time**

**Syntax**

```c
#include <time.h>

char *ctime(const time_t *timer);
```

**Syntax for C++**

```c++
#include <cstdio>

char *std::ctime(const time_ *timer);
```

**Defined in**

ctime.c in rts.src

**Description**

The `ctime` function converts a calendar time (pointed to by `timer`) to local time in the form of a string. This is equivalent to:

```
asctime(localtime(timer))
```

The function returns the pointer returned by the `asctime` function.

For more information about the functions and types that the `time.h` header declares and defines, see section 7.3.17, *Time Functions (time.h)*, on page 7-27.

difftime

**Time Difference**

**Syntax**

```c
#include <time.h>

double difftime(time_t time1, time_t time0);
```

**Syntax for C++**

```c++
#include <cstdio>

double std::difftime(time_t time1, time_t time0);
```

**Defined in**
difftime.c in rts.src

**Description**

The `difftime` function calculates the difference between two calendar times, `time1` minus `time0`. The return value expresses seconds.

For more information about the functions and types that the `time.h` header declares and defines, see section 7.3.17, *Time Functions (time.h)*, on page 7-27.
Division

Syntax

```c
#include <stdlib.h>

div_t div(int numer, int denom);
ldiv_t ldiv(long numer, long denom);
lldiv_t lldiv(long long numer, long long denom);
```

Syntax for C++

```cpp
#include <cstdlib>

div_t std::div(int numer, int denom);
ldiv_t std::ldiv(long numer, long denom);
lldiv_t std::ldiv(long long numer, long long denom);
```

Defined in

div.c in rts.src

Description

Two functions support integer division by returning `numer` (numerator) divided by `denom` (denominator). You can use these functions to get both the quotient and the remainder in a single operation.

- The `div` function performs integer division. The input arguments are integers; the function returns the quotient and the remainder in a structure of type `div_t`. The structure is defined as follows:

  ```c
  typedef struct
  {
    int quot;   /*  quotient */
    int rem;    /* remainder */
  } div_t;
  ```

- The `ldiv` function performs long integer division. The input arguments are long integers; the function returns the quotient and the remainder in a structure of type `ldiv_t`. The structure is defined as follows:

  ```c
  typedef struct
  {
    long int quot;   /*  quotient */
    long int rem;    /* remainder */
  } ldiv_t;
  ```

- The `lldiv` function performs long long integer division. The input arguments are long long integers; the function returns the quotient and the remainder in a structure of type `lldiv_t`. The structure is defined as follows:

  ```c
  typedef struct {long long int quot, rem; } lldiv_t;
  ```

The sign of the quotient is negative if either but not both of the operands is negative. The sign of the remainder is the same as the sign of the dividend.
exit

Normal Termination

Syntax
```c
#include <stdlib.h>

void exit(int status);
```

Syntax for C++
```c
#include <cstdio>

void std::exit(int status);
```

Defined in
exit.c in rts.src

Description
The exit function terminates a program normally. All functions registered by the atexit function are called in reverse order of their registration. The exit function can accept EXIT_FAILURE as a value. (See the abort function on page 7-39).

You can modify the exit function to perform application-specific shut-down tasks. The unmodified function simply runs in an infinite loop until the system is reset.

The exit function cannot return to its caller.

exp

Exponential

Syntax
```c
#include <math.h>

double exp(double x);
```

Syntax for C++
```c
#include <cstdio>

double std::exp(double x);
```

Defined in
exp.c in rts.src

Description
The exp function returns the exponential function of real number x. The return value is the number e raised to the power x. A range error occurs if the magnitude of x is too large.

Example
```c
double x, y;

x = 2.0;

y = exp(x); /* y = 7.38, which is e**2.0 */
```
**fabs**  
**Absolute Value**

**Syntax**
```c
#include <math.h>

double fabs(double x);
```

**Syntax for C++**
```cpp
#include <cstdio>

double std::fabs(double x);
```

**Defined in**
fabs.c in rts.src

**Description**
The fabs function returns the absolute value of a floating-point number, x.

**Example**
```c
double x, y;
x = -57.5;
y = fabs(x); /* return value = +57.5 */
```

---

**far.peek/ far.peek.l**  
**Read From an Extended Memory Address**

**Syntax**
```c
#include <extaddr.h>

extern int far.peek(FARPTR x);
extern unsigned long far.peek.l(FARPTR x);
```

**Defined in**
extaddr.asm in rts.src

**Description**
The far.peek function reads an integer from an extended memory address. The far.peek.l function reads an unsigned long from an extended memory address.

**Example**
```c
int ilocal;
int llocal;
FARPTR iptr = (FARPTR) &ival;
FARPTR lptr = (FARPTR) &lval;
far_poke(iptr, 100);
ilocal = far.peek(iptr) + 10;
far_poke_l(lptr, 0x7fffffff);
llocal = far.peek_l(lptr) + 1;
```
far_poke/ far_poke_l

Write to an Extended Memory Address

Syntax

```c
#include <extaddr.h>

extern void far_poke(FARPTR x, int x);
extern void far_poke_l(FARPTR x, unsigned long x);
```

Defined in

extaddr.asm in rts.src

Description

The far_poke function writes an integer to an extended memory address. The far_poke_l function writes an unsigned long to an extended memory address.

Example

See the example code for far_peek.

far_memcpy

Memory Block Copy Between Extended Memory Addresses

Syntax

```c
#include <extaddr.h>

extern void far_memcpy(FARPTR *s1, FARPTR *s2, int n);
```

Defined in

extaddr.asm in rts.src

Description

The far_memcpy function copies n integers from the object that s2 points to into the object that s1 points to. If you attempt to copy characters of overlapping objects, the function’s behavior is undefined.

Example

```c
int a[10] = {0,1,2,3,4,5,6,7,8,9};
int b[10];
far_memcpy((FARPTR) &b, (FARPTR) &a, 10);
```

far_near_memcpy/ near_far_memcpy

Memory Block Copy from/to Extended Memory

Syntax

```c
#include <extaddr.h>

extern void far_near_memcpy(void *, FARPTR, int);
extern void near_far_memcpy(FARPTR, void *, int);
```

Defined in

extaddr.asm in rts.src
**fclose**

*Close File*

**Description**
The fclose function flushes the stream that _fp points to and closes the file associated with that stream.

**Syntax**
```c
#include <stdio.h>
int fclose(FILE *fp);
```

**Syntax for C++**
```cpp
#include <cstdio>
int std::fclose(FILE *fp);
```

**Defined in**
fclose.c in rts.src

**Test EOF Indicator**

**feof**

**Description**
The feof function tests the EOF indicator for the stream pointed to by _fp.

**Syntax**
```c
#include <stdio.h>
int feof(FILE *fp);
```

**Syntax for C++**
```cpp
#include <cstdio>
int std::feof(FILE *fp);
```

**Defined in**
feof.c in rts.src

**Test Error Indicator**

**ferror**

**Description**
The ferror function tests the error indicator for the stream pointed to by _fp.

**Syntax**
```c
#include <stdio.h>
int ferror(FILE *fp);
```

**Syntax for C++**
```cpp
#include <cstdio>
int std::ferror(FILE *fp);
```

**Defined in**
ferror.c in rts.src

---

**Description**
The far_near_memcpyp function copies integers from an extended memory address to page 0. The near_far_memcpyp function copies integers from page 0 to an extended memory address.

**Example**
```c
char c[12] = {"test string"};
char d[12];
far_near_memcpyp((void *) d, (FARPTR) &c, 12);
```
**fflush**

**Flush I/O Buffer**

**Syntax**
```
#include <stdio.h>
int fflush(register FILE *_fp);
```

**Syntax for C++**
```
#include <cstdio>
int std::fflush(register FILE *fp);
```

**Defined in**
fflush.c in rts.src

**Description**
The fflush function flushes the I/O buffer for the stream pointed to by _fp.

---

**fgetc**

**Read Next Character**

**Syntax**
```
#include <stdio.h>
int fgetc(register FILE *fp);
```

**Syntax for C++**
```
#include <cstdio>
int std::fgetc(register FILE *fp);
```

**Defined in**
fgetc.c in rts.src

**Description**
The fgetc function reads the next character in the stream pointed to by _fp.

---

**fgetpos**

**Store Object**

**Syntax**
```
#include <stdio.h>
int fgetpos(FILE *fp, fpos_t *pos);
```

**Syntax for C++**
```
#include <cstdio>
int std::fgetpos(FILE *fp, fpos_t *pos);
```

**Defined in**
fgetpos.c in rts.src

**Description**
The fgetpos function stores the object pointed to by pos to the current value of the file position indicator for the stream pointed to by _fp.
fgets

Read Next Characters

Syntax
#include <stdio.h>
char *fgets(char *ptr, register int _size, register FILE *fp);

Syntax for C++
#include <cstdio>
char *std::fgets(char *ptr, register int _size, register FILE *fp);

Defined in fgets.c in rts.src

Description
The fgets function reads the specified number of characters from the stream pointed to by _fp. The characters are placed in the array named by _ptr. The number of characters read is _size −1.

floor

Floor

Syntax
#include <math.h>
double floor(double x);

Syntax for C++
#include <cstdio>
double std::floor(double x);

Defined in floor.c in rts.src

Description
The floor function returns a floating-point number that represents the largest integer less than or equal to x.

Example
double answer;
answer = floor(3.1415); /* answer = 3.0 */
answer = floor(-3.5); /* answer = -4.0 */

fmod

Floating-Point Remainder

Syntax
#include <math.h>
double fmod(double x, double y);

Syntax for C++
#include <cstdio>
double std::fmod(double x, double y);

Defined in fmod.c in rts.src

Description
The fmod function returns the floating-point remainder of x divided by y. If y == 0, the function returns 0.

Example
double x, y, r;
x = 11.0;
y = 5.0;
r = fmod(x, y); /* fmod returns 1.0 */
fopen

Open File

Syntax

```c
#include <stdio.h>
FILE *fopen(const char *fname, const char *mode);
```

Syntax for C++

```c
#include <cstdio>
FILE *std::fopen(const char *fname, const char *mode);
```

Defined in

fopen.c in rts.src

Description

The fopen function opens the file that `fname` points to. The string pointed to by `mode` describes how to open the file. Under UNIX, specify mode as `rb` for a binary read or `wb` for a binary write.

fprintf

Write Stream

Syntax

```c
#include <stdio.h>
int fprintf(FILE *fp, const char *format, ...);
```

Syntax for C++

```c
#include <cstdio>
int std::fprintf(FILE *fp, const char *format, ...);
```

Defined in

fprintf.c in rts.src

Description

The fprintf function writes to the stream pointed to by `fp`. The string pointed to by `format` describes how to write the stream.

fputc

Write Character

Syntax

```c
#include <stdio.h>
int fputc(int _c, register FILE *fp);
```

Syntax for C++

```c
#include <cstdio>
int std::fputc(int _c, register FILE *fp);
```

Defined in

fputc.c in rts.src

Description

The fputc function writes a character to the stream pointed to by `fp`. 
**fputs**

*Write String*

**Syntax**

```c
#include <stdio.h>

int fputs(const char *ptr, register FILE *fp);
```

**Syntax for C++**

```c
#include <cstdio>

int std::fputs(const char *ptr, register FILE *fp);
```

**Defined in**
fputs.c in rts.src

**Description**
The fputs function writes the string pointed to by _ptr to the stream pointed to by _fp.

---

**fread**

*Read Stream*

**Syntax**

```c
#include <stdio.h>

size_t fread(void *ptr, size_t size, size_t count, FILE *fp);
```

**Syntax for C++**

```c
#include <cstdio>

size_t std::fread(void *ptr, size_t size, size_t count, FILE *fp);
```

**Defined in**
fread.c in rts.src

**Description**
The fread function reads from the stream pointed to by _fp. The input is stored in the array pointed to by _ptr. The number of objects read is _count. The size of the objects is _size.

---

**Note: Using fread When C55x char Differs from Host’s Bytes**

For details on handling I/O when the C55x char is different than your host’s byte, refer to *Reading and Writing Binary Files on Targets with More Than 8-bit Chars* (Literature Number SPRA757).
free

Deallocate Memory

Syntax

```c
#include <stdlib.h>

void free(void *ptr);
```

Syntax for C++

```c
#include <cstdlib>

void std::free(void *ptr);
```

Defined in memory.c in rts.src

Description

The free function deallocates memory space (pointed to by ptr) that was previously allocated by a malloc, calloc, or realloc call. This makes the memory space available again. If you attempt to free unallocated space, the function takes no action and returns. For more information, see section 6.1.6, Dynamic Memory Allocation, on page 6-7.

Example

This example allocates ten bytes and then frees them.

```c
char *x;
x = malloc(10); /* allocate 10 bytes */
free(x); /* free 10 bytes */
```

freopen

Open File

Syntax

```c
#include <stdio.h>

FILE *freopen(const char *fname, const char *_mode, register FILE *_fp);
```

Syntax for C++

```c
#include <cstdio>

FILE *std::freopen(const char *fname, const char *mode, register FILE *fp);
```

Defined in freopen.c in rts.src

Description

The freopen function opens the file pointed to by _fname, and associates with it the stream pointed to by _fp. The string pointed to by _mode describes how to open the file.
frexp  

**Fraction and Exponent**

**Syntax**

```c
#include <math.h>
double frexp(double value, int *exp);
```

**Syntax for C++**

```cpp
#include <cmath>
double std::frexp(double value, int *exp);
```

**Defined in**

frexp.c in rts.src

**Description**

The frexp function breaks a floating-point number into a normalized fraction and the integer power of 2. The function returns a value with a magnitude in the range \([1/2, 1]\) or 0, so that value = \(x \times 2^{\exp}\). The frexp function stores the power in the int pointed to by exp. If value is 0, both parts of the result are 0.

**Example**

```c
double fraction;
int exp;
fraction = frexp(3.0, &exp);
/* after execution, fraction is .75 and exp is 2 */
```

fscanf  

**Read Stream**

**Syntax**

```c
#include <stdio.h>
int fscanf(FILE *fp, const char *_fmt, ...);
```

**Syntax for C++**

```cpp
#include <cstdio>
int std::fscanf(FILE *fp, const char *_fmt, ...);
```

**Defined in**

fscanf.c in rts.src

**Description**

The fscanf function reads from the stream pointed to by _fp. The string pointed to by _fmt describes how to read the stream.

fseek  

**Set File Position Indicator**

**Syntax**

```c
#include <stdio.h>
int fseek(register FILE *fp, long _offset, int _ptrname);
```

**Syntax for C++**

```cpp
#include <cstdio>
int std::fseek(register FILE *fp, long _offset, int _ptrname);
```

**Defined in**

fseek.c in rts.src

**Description**

The fseek function sets the file position indicator for the stream pointed to by _fp. The position is specified by _ptrname. For a binary file, use _offset to position the indicator from _ptrname. For a text file, offset must be 0.
fsetpos

**Set File Position Indicator**

**Syntax**

```c
#include <stdio.h>

int fsetpos(FILE *fp, const fpos_t *pos);
```

**Syntax for C++**

```cpp
#include <cstdio>

int std::fsetpos(FILE *fp, const fpos_t *pos);
```

**Defined in**

fsetpos.c in rts.src

**Description**

The fsetpos function sets the file position indicator for the stream pointed to by *fp to *pos. The pointer *pos must be a value from fgetpos() on the same stream.

ftell

**Get Current File Position Indicator**

**Syntax**

```c
#include <stdio.h>

long ftell(FILE *fp);
```

**Syntax for C++**

```cpp
#include <cstdio>

long ftell(FILE *fp);
```

**Defined in**

ftell.c in rts.src

**Description**

The ftell function gets the current value of the file position indicator for the stream pointed to by *fp.

fwrite

**Write Block of Data**

**Syntax**

```c
#include <stdio.h>

size_t fwrite(const void *ptr, size_t size, size_t count, register FILE *fp);
```

**Syntax for C++**

```cpp
#include <cstdio>

size_t std::fwrite(const void *ptr, size_t size, size_t count, register FILE *fp);
```

**Defined in**

fwrite.c in rts.src

**Description**

The fwrite function writes a block of data from the memory pointed to by *ptr to the stream that *fp points to.
**getenv**

*Get Environment Information*

**Syntax**

```c
#include <stdlib.h>

char *getenv(const char * _string);
```

**Syntax for C++**

```cpp
#include <cstdlib>

char *std::getenv(const char * _string);
```

**Defined in**

trgdrv.c in rts.src

**Description**

The getenv function returns the environment information for the variable associated with _string.

---

**getc**

*Read Next Character*

**Syntax**

```c
#include <stdio.h>

int getc(FILE * _fp);
```

**Syntax for C++**

```cpp
#include <cstdio>

int std::getc(FILE * _fp);
```

**Defined in**

fgetc.c in rts.src

**Description**

The getc function reads the next character in the file pointed to by _fp.

---

**getchar**

*Read Next Character From Standard Input*

**Syntax**

```c
#include <stdio.h>

int getchar(void);
```

**Syntax for C++**

```cpp
#include <cstdio>

int std::getchar(void);
```

**Defined in**

fgetc.c in rts.src

**Description**

The getchar function reads the next character from the standard input device.
gets

Read Next From Standard Input

Syntax

#include <stdio.h>
char *gets(char *_ptr);

Syntax for C++

#include <cstdio>
char *std::gets(char *ptr);

Defined in
fgets.c in rts.src

Description
The gets function reads an input line from the standard input device. The characters are placed in the array named by _ptr.

gmtime

Greenwich Mean Time

Syntax

#include <time.h>
struct tm *gmtime(const time_t *timer);

Syntax for C++

#include <ctime>
struct tm *std::gmtime(const time_t *timer);

Defined in
gmtime.c in rts.src

Description
The gmtime function converts a calendar time (pointed to by timer) into a broken-down time, which is expressed as Greenwich Mean Time.

For more information about the functions and types that the time.h header declares and defines, see section 7.3.17, Time Functions (time.h), on page 7-27.
### isxxx

#### Character Typing

**Syntax**

```c
#include <ctype.h>

int isalnum(int c);  // Identifies alphanumeric ASCII characters
int isalpha(int c);  // Identifies alphabetic ASCII characters
int isascii(int c);  // Identifies ASCII characters
int iscntrl(int c);  // Identifies control characters
int isdigit(int c);  // Identifies numeric characters
int isgraph(int c);  // Identifies any nonspace character
int islower(int c);  // Identifies lowercase alphabetic ASCII characters
int isprint(int c);  // Identifies printable ASCII characters
int ispunct(int c);  // Identifies ASCII punctuation characters
int isspace(int c);  // Identifies ASCII tab and space bar, carriage return, form feed, and new line characters
```

**Syntax for C++**

```cpp
#include <cctype>

int std::isalnum(int c);  // Identifies alphanumeric ASCII characters
int std::isalpha(int c);  // Identifies alphabetic ASCII characters
int std::isascii(int c);  // Identifies ASCII characters
int std::iscntrl(int c);  // Identifies control characters
int std::isdigit(int c);  // Identifies numeric characters
int std::isgraph(int c);  // Identifies any nonspace character
int std::islower(int c);  // Identifies lowercase alphabetic ASCII characters
int std::isprint(int c);  // Identifies printable ASCII characters
int std::ispunct(int c);  // Identifies ASCII punctuation characters
int std::isspace(int c);  // Identifies ASCII tab and space bar, carriage return, form feed, and new line characters
```

**Defined in**

isxxx.c and ctype.c in rts.src

Also defined in ctype.h/cctype as macros

**Description**

These functions test a single argument to see if it is a particular type of character — alphabetic, alphanumeric, numeric, ASCII, etc. If the test is true, the function returns a nonzero value; if the test is false, the function returns 0. The character typing functions include:

- `isalnum`: Identifies alphanumeric ASCII characters (tests for any character for which `isalpha` or `isdigit` is true)
- `isalpha`: Identifies alphabetic ASCII characters (tests for any character for which `islower` or `isupper` is true)
- `isascii`: Identifies ASCII characters (any character from 0–127)
- `iscntrl`: Identifies control characters (ASCII characters 0–31 and 127)
- `isdigit`: Identifies numeric characters between 0 and 9 (inclusive)
- `isgraph`: Identifies any nonspace character
- `islower`: Identifies lowercase alphabetic ASCII characters
- `isprint`: Identifies printable ASCII characters, including spaces (ASCII characters 32–126)
- `ispunct`: Identifies ASCII punctuation characters
- `isspace`: Identifies ASCII tab (horizontal or vertical), space bar, carriage return, form feed, and new line characters
isupper  Identifies uppercase ASCII alphabetic characters
isxdigit  Identifies hexadecimal digits (0–9, a–f, A–F)

The C compiler also supports a set of macros that perform these same functions. The macros have the same names as the functions but are prefixed with an underscore; for example, _isascii is the macro equivalent of the isascii function. In general, the macros execute more efficiently than the functions.

See abs/labs on page 7–37.

Multiply by a Power of Two

Syntax
#include <math.h>

double ldexp(double x, int exp);

Syntax for C++
#include <cmath>

double std::ldexp(double x, int exp);

Defined in ldexp.c in rts.src

Description
The ldexp function multiplies a floating-point number by the power of 2 and returns \( x \times 2^{\text{exp}} \). The \( \text{exp} \) can be a negative or a positive value. A range error occurs if the result is too large.

Example
double result;

\[
\begin{align*}
\text{result} &= \text{ldexp}(1.5, 5); \quad \text{/* result is 48.0 */} \\
\text{result} &= \text{ldexp}(6.0, -3); \quad \text{/* result is 0.75 */}
\end{align*}
\]

See div/ldiv on page 7–47
**localtime**  

*Local Time*

**Syntax**

```c
#include <time.h>

struct tm *localtime(const time_t *timer);
```

**Syntax for C++**

```c
#include <ctime>

struct tm *std::localtime(const time_t *timer);
```

**Defined in**

localtime.c in rts.src

**Description**

The `localtime` function converts a calendar time (pointed to by `timer`) into a broken-down time, which is expressed as local time. The function returns a pointer to the converted time.

For more information about the functions and types that the `time.h` header declares and defines, see section 7.3.17, *Time Functions (Time.h)* on page 7-27.

---

**log**  

*Natural Logarithm*

**Syntax**

```c
#include <math.h>

double log(double x);
```

**Syntax for C++**

```c
#include <cmath>

double std::log(double x);
```

**Defined in**

log.c in rts.src

**Description**

The `log` function returns the natural logarithm of a real number `x`. A domain error occurs if `x` is negative; a range error occurs if `x` is 0.

```c
defloat x, y;

x = 2.718282;
y = log(x); /* Return value = 1.0 */
```
log10

**Common Logarithm**

**Syntax**

```c
#include <math.h>

double log10(double x);
```

**Syntax for C++**

```c
#include <cmath>

double std::log10(double x);
```

**Defined in**

log10.c in rts.src

**Description**

The `log10` function returns the base-10 logarithm of a real number `x`. A domain error occurs if `x` is negative; a range error occurs if `x` is 0.

**Example**

```c
float x, y;

x = 10.0;
y = log(x); /* Return value = 1.0 */
```

---

**ltoa**

**Long Integer to ASCII**

**Syntax**

no prototype provided

```c
int ltoa(long val, char *buffer);
```

**Syntax for C++**

no prototype provided

```c
int ltoa(long val, char *buffer);
```

**Defined in**

ltoa.c in rts.src

**Description**

The `ltoa` function is a nonstandard (non-ISO) function and is provided for compatibility. The standard equivalent is `sprintf`. The function is not prototyped in rts.src. The `ltoa` function converts a long integer `n` to an equivalent ASCII string and writes it into the buffer. If the input number `val` is negative, a leading minus sign is output. The `ltoa` function returns the number of characters placed in the buffer.

See `setjmp/longjmp` on page 7-78.
malloc

Allocate Memory

Syntax

```c
#include <stdlib.h>

void *malloc(size_t size);
```

Syntax for C++

```c++
#include <cstdlib>

void *std::malloc(size_t size);
```

Defined in

memory.c in rts.src

Description

The malloc function allocates space for an object of size 16-bit bytes and returns a pointer to the space. If malloc cannot allocate the packet (that is, if it runs out of memory), it returns a null pointer (0). This function does not modify the memory it allocates.

The memory that malloc uses is in a special memory pool or heap. The constant `_SYSMEM_SIZE` defines the size of the heap as 2000 bytes. You can change this amount at link time by invoking the linker with the `-heap` option and specifying the desired size of the heap (in bytes) directly after the option. For more information, see section 6.1.6, Dynamic Memory Allocation, on page 6-7.

memchr

Find First Occurrence of Byte

Syntax

```c
#include <string.h>

void *memchr(const void *cs, int c, size_t n);
```

Syntax for C++

```c++
#include <cstring>

void *std::memchr(const void *cs, int c, size_t n);
```

Defined in

memchr.c in rts.src

Description

The memchr function finds the first occurrence of `c` in the first `n` characters of the object that `cs` points to. If the character is found, memchr returns a pointer to the located character; otherwise, it returns a null pointer (0).

The memchr function is similar to strchr, except that the object that memchr searches can contain values of 0 and `c` can be 0.
memcmp

Memory Compare

Syntax

```c
#include <string.h>

int memcmp(const void *cs, const void *ct, size_t n);
```

Syntax for C++

```cpp
#include <cstring>

int std::memcmp(const void *cs, const void *ct, size_t n);
```

Defined in

memcmp.c in rts.src

Description

The memcmp function compares the first n characters of the object that ct points to with the object that cs points to. The function returns one of the following values:

- `< 0` if *cs* is less than *ct*
- `0` if *cs* is equal to *ct*
- `> 0` if *cs* is greater than *ct*

The memcmp function is similar to strncmp, except that the objects that memcmp compares can contain values of 0.

memcpy

Memory Block Copy — Nonoverlapping

Syntax

```c
#include <string.h>

void *memcpy(void *s1, const void *s2, size_t n);
```

Syntax for C++

```cpp
#include <cstring>

void *std::memcpy(void *s1, const void *s2, size_t n);
```

Defined in

memcpy.c in rts.src

Description

The memcpy function copies n characters from the object that s2 points to into the object that s1 points to. If you attempt to copy characters of overlapping objects, the function’s behavior is undefined. The function returns the value of s1.

The memcpy function is similar to strncpy, except that the objects that memcpy copies can contain values of 0.
### memmove

**Memory Block Copy — Overlapping**

**Syntax**

```c
#include <string.h>

void *memmove(void *s1, const void *s2, size_t n);
```

**Syntax for C++**

```c++
#include <cstring>

void *std::memmove(void *s1, const void *s2, size_t n);
```

**Defined in**

memmove.c in rts.src

**Description**

The `memmove` function moves `n` characters from the object that `s2` points to into the object that `s1` points to; the function returns the value of `s1`. The `memmove` function correctly copies characters between overlapping objects.

### memset

**Duplicate Value in Memory**

**Syntax**

```c
#include <string.h>

void *memset(void *mem, register int ch, size_t length);
```

**Syntax for C++**

```c++
#include <cstring>

void *std::memset(void *mem, register int ch, size_t length);
```

**Defined in**

memset.c in rts.src

**Description**

The `memset` function copies the value of `ch` into the first `length` characters of the object that `mem` points to. The function returns the value of `mem`.

### mktime

**Convert to Calendar Time**

**Syntax**

```c
#include <time.h>

time_t *mktime(struct tm *timeptr);
```

**Syntax for C++**

```c++
#include <ctime>

time_t *std::mktime(struct tm *timeptr);
```

**Defined in**

mktime.c in rts.src

**Description**

The `mktime` function converts a broken-down time, expressed as local time, into proper calendar time. The `timeptr` argument points to a structure that holds the broken-down time.
The function ignores the original values of tm_wday and tm_yday and does not restrict the other values in the structure. After successful completion of time conversions, tm_wday and tm_yday are set appropriately, and the other components in the structure have values within the restricted ranges. The final value of tm_mday is not sent until tm_mon and tm_year are determined.

The return value is encoded as a value of type time_t. If the calendar time cannot be represented, the function returns the value −1.

For more information about the functions and types that the time.h header declares and defines, see section 7.3.17, Time Functions (time.h), on page 7-27.

**Example**

This example determines the day of the week that July 4, 2001, falls on.

```c
#include <time.h>
static const char *const wday[] = {
    "Sunday", "Monday", "Tuesday", "Wednesday",
    "Thursday", "Friday", "Saturday" 
};

struct tm time_str;

time_str.tm_year = 2001 - 1900;
time_str.tm_mon = 7;
time_str.tm_mday = 4;
time_str.tm_hour = 0;
time_str.tm_min = 0;
time_str.tm_sec = 1;
time_str.tm_isdst = 1;
mktime(&time_str);

/* After calling this function, time_str.tm_wday contains the day of the week for July 4, 2001 */
```
m{}

m{}

Syntax

#include <math.h>
double modf(double value, double *iptr);

Syntax for C++

#include <cmath>
double std::modf(double value, double *iptr);

Defined in

modf.c in rts.src

Description

The modf function breaks a value into a signed integer and a signed fraction. Each of the two parts has the same sign as the input argument. The function returns the fractional part of value and stores the integer as a double at the object pointed to by iptr.

Example

double value, ipart, fpart;
value = -3.1415;
fpart = modf(value, &ipart);

/* After execution, ipart contains -3.0, */
/* and fpart contains -0.1415. */

m{}

Reset Dynamic Memory Pool

Syntax

no prototype provided

void minit(void);

Defined in

memory.c in rts.src

Description

The minit function resets all the space that was previously allocated by calls to the malloc, calloc, or realloc functions.

The memory that minit uses is in a special memory pool or heap. The constant _SYSMEM_SIZE defines the size of the heap as 2000 bytes. You can change this amount at link time by invoking the linker with the -heap option and specifying the desired size of the heap (in bytes) directly after the option. For more information, see section 6.1.6, Dynamic Memory Allocation, on page 6-7.

Note: No Previously Allocated Objects are Available After minit

Calling the minit function makes all the memory space in the heap available again. Any objects that you allocated previously will be lost; do not try to access them.

m{}

Signed Integer and Fraction

Note: No Previously Allocated Objects are Available After minit

Calling the minit function makes all the memory space in the heap available again. Any objects that you allocated previously will be lost; do not try to access them.
### perror

**Map Error Number**

**Syntax**
```c
#include <stdio.h>

void perror(const char *s);
```

**Syntax for C++**
```cpp
#include <cstdio>

void std::perror(const char *s);
```

**Defined in**
 perror.c in rts.src

**Description**
The perror function maps the error number in s to a string and prints the error message.

### pow

**Raise to a Power**

**Syntax**
```c
#include <math.h>

double pow(double x, double y);
```

**Syntax for C++**
```cpp
#include <cmath>

double std::pow(double x, double y);
```

**Defined in**
pow.c in rts.src

**Description**
The pow function returns x raised to the power y. A domain error occurs if x = 0 and y ≤ 0, or if x is negative and y is not an integer. A range error occurs if the result is too large to represent.

**Example**
```c
double x, y, z;
x = 2.0;
y = 3.0;
x = pow(x, y); /* return value = 8.0 */
```

### printf

**Write to Standard Output**

**Syntax**
```c
#include <stdio.h>

int printf(const char *format, ...);
```

**Syntax for C++**
```cpp
#include <cstdio>

int std::printf(const char *format, ...);
```

**Defined in**
printf.c in rts.src

**Description**
The printf function writes to the standard output device. The string pointed to by _format describes how to write the stream.
**putc**

*Write Character*

**Syntax**

```c
#include <stdio.h>
int putc(int _x, FILE *fp);
```

**Syntax for C++**

```c
#include <cstdio>
int std::putc(int _x, FILE *fp);
```

**Defined in**

putc.c in rts.src

**Description**

The putc function writes a character to the stream pointed to by _fp.

---

**putchar**

*Write Character to Standard Output*

**Syntax**

```c
#include <stdio.h>
int putchar(int _x);
```

**Syntax for C++**

```c
#include <cstdio>
int std::putchar(int _x);
```

**Defined in**

putchar.c in rts.src

**Description**

The putchar function writes a character to the standard output device.

---

**puts**

*Write to Standard Output*

**Syntax**

```c
#include <stdio.h>
int puts(const char *ptr);
```

**Syntax for C++**

```c
#include <cstdio>
int std::puts(const char *ptr);
```

**Defined in**

puts.c in rts.src

**Description**

The puts function writes the string pointed to by _ptr to the standard output device.
**qsort**  

**Array Sort**

**Syntax**

```c
#include <stdlib.h>
void qsort(void *base, size_t nmemb, size_t size, int (*compar) ());
```

**Syntax for C++**

```c
#include <cstdlib>
void std::qsort(void *base, size_t nmemb, size_t size, int (*compar) ());
```

**Defined in**

qsort.c in rts.src

**Description**

The `qsort` function sorts an array of `nmemb` members. Argument `base` points to the first member of the unsorted array; argument `size` specifies the size of each member.

This function sorts the array in ascending order.

Argument `compar` points to a function that compares key to the array elements. The comparison function should be declared as:

```c
int cmp(const void *ptr1, const void *ptr2)
```

The `cmp` function compares the objects that `ptr1` and `ptr2` point to and returns one of the following values:

- `< 0` if `ptr1` is less than `ptr2`
- `0` if `ptr1` is equal to `ptr2`
- `> 0` if `ptr1` is greater than `ptr2`
### rand/srand

#### Random Integer

**Syntax**
```
#include <stdlib.h>

int rand(void);
void srand(unsigned int seed);
```

**Syntax for C++**
```
#include <cstdlib>

int std::rand(void);
void std::srand(unsigned int seed);
```

**Defined in**
`rand.c` in rts.src

**Description**
Two functions work together to provide pseudorandom sequence generation:

- The `rand` function returns pseudorandom integers in the range `0–RAND_MAX`.
- The `srand` function sets the value of seed so that a subsequent call to the `rand` function produces a new sequence of pseudorandom numbers. The `srand` function does not return a value.

If you call `rand` before calling `srand`, `rand` generates the same sequence it would produce if you first called `srand` with a seed value of 1. If you call `srand` with the same seed value, `rand` generates the same sequence of numbers.

### realloc

#### Change Heap Size

**Syntax**
```
#include <stdlib.h>

void *realloc(void *packet, size_t size);
```

**Syntax for C++**
```
#include <cstdlib>

void *std::realloc(void *packet, size_t size);
```

**Defined in**
`memory.c` in rts.src

**Description**
The `realloc` function changes the size of the allocated memory pointed to by `packet` to the size specified in bytes by `size`. The contents of the memory space (up to the lesser of the old and new sizes) is not changed.

- If packet is 0, `realloc` behaves like `malloc`.
- If packet points to unallocated space, `realloc` takes no action and returns 0.
If the space cannot be allocated, the original memory space is not changed, and realloc returns 0.

If size == 0 and packet is not null, realloc frees the space that packet points to.

If the entire object must be moved to allocate more space, realloc returns a pointer to the new space. Any memory freed by this operation is deallocated. If an error occurs, the function returns a null pointer (0).

The memory that calloc uses is in a special memory pool or heap. The constant __SYSMEM_SIZE defines the size of the heap as 2000 bytes. You can change this amount at link time by invoking the linker with the -heap option and specifying the desired size of the heap (in bytes) directly after the option. For more information, see section 6.1.6, Dynamic Memory Allocation, on page 6-7.

**Remove File**

**Syntax**

```c
#include <stdio.h>

int remove(const char *file);
```

**Syntax for C++**

```cpp
#include <cstdio>

int std::remove(const char *file);
```

**Defined in**

remove.c in rts.src

**Description**

The remove function makes the file pointed to by file no longer available by that name.

**Rename File**

**Syntax**

```c
#include <stdio.h>

int rename(const char *old_name, const char *new_name);
```

**Syntax for C++**

```cpp
#include <cstdio>

int std::rename(const char *old_name, const char *new_name);
```

**Defined in**

rename.c in rts.src

**Description**

The rename function renames the file pointed to by old_name. The new name is pointed to by new_name.
## rewind

**Position File Position Indicator to Beginning of File**

**Syntax**

```c
#include <stdio.h>

void rewind(register FILE *fp);
```

**Syntax for C++**

```c
#include <cstdio>

void std::rewind(register FILE *fp);
```

**Defined in**

rewind.c in rts.src

**Description**

The `rewind` function sets the file position indicator for the stream pointed to by `_fp` to the beginning of the file.

## scanf

**Read Stream From Standard Input**

**Syntax**

```c
#include <stdio.h>

int scanf(const char *fmt, ...);
```

**Syntax for C++**

```c
#include <cstdio>

int std::scanf(const char *fmt, ...);
```

**Defined in**

fscanf.c in rts.src

**Description**

The `scanf` function reads from the stream from the standard input device. The string pointed to by `_fmt` describes how to read the stream.

## setbuf

**Specify Buffer for Stream**

**Syntax**

```c
#include <stdio.h>

void setbuf(register FILE *fp, char *buf);
```

**Syntax for C++**

```c
#include <cstdio>

void std::setbuf(register FILE *fp, char *buf);
```

**Defined in**

setbuf.c in rts.src

**Description**

The `setbuf` function specifies the buffer used by the stream pointed to by `_fp`. If `_buf` is set to null, buffering is turned off. No value is returned.
setjmp/longjmp

Nonlocal Jumps

Syntax

```c
#include <setjmp.h>

int setjmp(jmp_buf env)
void longjmp(jmp_buf env, int _val)
```

Syntax for C++

```c
#include <csetjmp>

int std::setjmp(jmp_buf env)
void std::longjmp(jmp_buf env, int _val)
```

Defined in

setjmp.asm in rts.src

Description

The set jmp.h header defines one type, one macro, and one function for bypassing the normal function call and return discipline:

- The `jmp_buf` type is an array type suitable for holding the information needed to restore a calling environment.

- The `setjmp` macro saves its calling environment in the `jmp_buf` argument for later use by the `longjmp` function.

  If the return is from a direct invocation, the `setjmp` macro returns the value 0. If the return is from a call to the `longjmp` function, the `setjmp` macro returns a nonzero value.

- The `longjmp` function restores the environment that was saved in the `jmp_buf` argument by the most recent invocation of the `setjmp` macro. If the `setjmp` macro was not invoked, or if it terminated execution irregularly, the behavior of `longjmp` is undefined.

  After `longjmp` is completed, the program execution continues as if the corresponding invocation of `setjmp` had just returned the value specified by `_val`. The `longjmp` function does not cause `setjmp` to return a value of 0, even if `_val` is 0. If `_val` is 0, the `setjmp` macro returns the value 1.
**Example**

These functions are typically used to effect an immediate return from a deeply nested function call:

```c
#include <setjmp.h>
jmp_buf env;

main()
{
    int errcode;
    if ((errcode = setjmp(env)) == 0)
        nest1();
    else
        switch (errcode)
        . . .
}
. . .
nest42()
{
    if (input() == ERRCODE42)
        /* return to setjmp call in main */
        longjmp (env, ERRCODE42);
    . . .
}
```

---

**setvbuf**

*Define and Associate Buffer With Stream*

**Syntax**

```c
#include <stdio.h>

int setvbuf(register FILE *_fp, register char * _buf, register int _type,
            register size_t _size);
```

**Syntax for C++**

```c
#include <cstdio>

int std::setvbuf(register FILE * _fp, register char * _buf, register int _type,
                 register size_t _size);
```

**Defined in**

setvbuf.c in rts.src

**Description**

The setvbuf function defines and associates the buffer used by the stream pointed to by _fp. If _buf is set to null, a buffer is allocated. If _buf names a buffer, that buffer is used for the stream. The _size specifies the size of the buffer. The _type specifies the type of buffering as follows:

- _IOFBF: Full buffering occurs
- _IOLBF: Line buffering occurs
- _IONBF: No buffering occurs
sin

Sine

Syntax

```c
#include <math.h>

double sin(double x);
```

Syntax for C++

```c
#include <cmath>

double std::sin(double x);
```

Defined in

sin.c in rts.src

Description

The sin function returns the sine of a floating-point number x. The angle x is expressed in radians. An argument with a large magnitude may produce a result with little or no significance.

Example

```c
double radian, sval; /* sval is returned by sin */

radian = 3.1415927;

sval = sin(radian); /* -1 is returned by sin */
```

sinh

Hyperbolic Sine

Syntax

```c
#include <math.h>

double sinh(double x);
```

Syntax for C++

```c
#include <cmath>

double std::sinh(double x);
```

Defined in

sinh.c in rts.src

Description

The sinh function returns the hyperbolic sine of a floating-point number x. A range error occurs if the magnitude of the argument is too large.

Example

```c
double x, y;

x = 0.0;

y = sinh(x); /* return value = 0.0 */
```
**snprintf**

*Write Stream With Limit*

**Syntax**

```c
#include <stdio.h>

int snprintf(char _string, size_t n, const char *_format, ...);
```

**Syntax for C++**

```cpp
#include <cstdio>

int std::snprintf(char _string, size_t n, const char *_format, ...);
```

**Defined in**

snprintf.c in rts.src

**Description**
The snprintf function writes up to n characters to the array pointed to by _string. The string pointed to by _format describes how to write the stream. Returns the number of characters that would have been written if no limit had been placed on the string.

**sprintf**

*Write Stream*

**Syntax**

```c
#include <stdio.h>

int sprintf(char _string, const char *_format, ...);
```

**Syntax for C++**

```cpp
#include <cstdio>

int std::sprintf(char _string, const char *_format, ...);
```

**Defined in**

sprintf.c in rts.src

**Description**
The sprintf function writes to the array pointed to by _string. The string pointed to by _format describes how to write the stream.

**sqrt**

*Square Root*

**Syntax**

```c
#include <math.h>

double sqrt(double x);
```

**Syntax for C++**

```cpp
#include <cmath>

double std::sqrt(double x);
```

**Defined in**

sqrt.c in rts.src

**Description**
The sqrt function returns the nonnegative square root of a real number x. A domain error occurs if the argument is negative.

**Example**

```c
double x, y;

x = 100.0;
y = sqrt(x);   /* return value = 10.0 */
```
**srand**

*See rand/srand on page 7-75.*

**sscanf**

*Read Stream*

**Syntax**

```
#include <stdio.h>

int scanf(const char *str, const char *format, ...);
```

**Syntax for C++**

```
#include <cstdio>

int std::scanf(const char *str, const char *format, ...);
```

**Defined in**

sscanf.c in rts.src

**Description**

The `sscanf` function reads from the string pointed to by `str`. The string pointed to by `format` describes how to read the stream.

**strcat**

*Concatenate Strings*

**Syntax**

```
#include <string.h>

char *strcat(char *string1, char *string2);
```

**Syntax for C++**

```
#include <cstring>

char *std::strcat(char *string1, char *string2);
```

**Defined in**

strcat.c in rts.src

**Description**

The `strcat` function appends a copy of `string2` (including a terminating null character) to the end of `string1`. The initial character of `string2` overwrites the null character that originally terminated `string1`. The function returns the value of `string1`. 
**strchr**

*Find First Occurrence of a Character*

**Syntax**

```c
#include <string.h>

char *strchr(const char *string, int c);
```

**Syntax for C++**

```cpp
#include <cstring>

char *std::strchr(const char *string, int c);
```

**Defined in**

strchr.c in rts.src

**Description**

The `strchr` function finds the first occurrence of `c` in `string`. If `strchr` finds the character, it returns a pointer to the character; otherwise, it returns a null pointer (0).

**Example**

```c
char *a = "When zz comes home, the search is on for zs."
char *b;
char the_z = 'z';

b = strchr(a, the_z);
```

After this example, `*b` points to the first `z` in `zz`.

---

**Example**

In the following example, the character strings pointed to by *a, *b, and *c were assigned to point to the strings shown in the comments. In the comments, the notation “\0” represents the null character:

```c
char *a, *b, *c;

/* a −−> "The quick black fox\0" */
/* b −−> " jumps over \0" */
/* c −−> "the lazy dog.\0" */
strcat (a, b);
/* a −−> "The quick black fox jumps over \0" */
/* b −−> " jumps over \0" */
/* c −−> "the lazy dog.\0" */
strcat (a, c);
/* a−−> "The quick black fox jumps over the lazy dog.\0"*/
/* b −−> " jumps over \0" */
/* c −−> "the lazy dog.\0" */
```
**strcmp/strcoll**

*String Compare*

**Syntax**

```c
#include <string.h>

int strcmp(const char *string1, const char *string2);
int strcoll(const char *string1, const char *string2);
```

**Syntax for C++**

```cpp
#include <cstring>

int std::strcmp(const char *string1, const char *string2);
int std::strcoll(const char *string1, const char *string2);
```

**Defined in**

strcmp.c in rts.src

**Description**

The strcmp and strcoll functions compare string2 with string1. The functions are equivalent; both functions are supported to provide compatibility with ISO C.

The functions return one of the following values:

- `< 0` if `*string1` is less than `*string2`
- `0` if `*string1` is equal to `*string2`
- `> 0` if `*string1` is greater than `*string2`

**Example**

```c
char *stra = "why ask why";
char *strb = "just do it";
char *strc = "why ask why";

if (strcmp(stra, strb) > 0)
    { /* statements here will be executed */
    }
if (strcoll(stra, strc) == 0)
    { /* statements here will be executed also */
    }
```
**Strcpy**

*String Copy*

**Syntax**

```c
#include <string.h>
char *strcpy(char *dest, const char *src);
```

**Syntax for C++**

```c
#include <cstring>
char *std::strcpy(char *dest, const char *src);
```

**Defined in**

strncpy.c in rts.src

**Description**

The `strcpy` function copies `s2` (including a terminating null character) into `s1`. If you attempt to copy strings that overlap, the function's behavior is undefined. The function returns a pointer to `s1`.

**Example**

In the following example, the strings pointed to by `*a` and `*b` are two separate and distinct memory locations. In the comments, the notation `\0` represents the null character:

```c
char a[] = "The quick black fox"
char b[] = " jumps over ";
/* a --> "The quick black fox\0" */
/* b --> " jumps over \0" */
strcpy(a, b);
/* a --> " jumps over \0" */
/* b --> " jumps over \0" */
```

---

**Strcspn**

*Find Number of Unmatching Characters*

**Syntax**

```c
#include <string.h>
size_t strcspn(const char *string, const char *chs);
```

**Syntax for C++**

```c
#include <cstring>
size_t std::strcspn(const char *string, const char *chs);
```

**Defined in**

strcspn.c in rts.src

**Description**

The `strcspn` function returns the length of the initial segment of `string`, which is made up entirely of characters that are not in `chs`. If the first character in `string` is in `chs`, the function returns 0.

**Example**

```c
char *stra = "who is there?"
char *strb = "abcdefhijklmnopqrstuvwxyz"
char *strc = "abcdefg"
size_t length;
length = strcspn(stra, strb); /* length = 0 */
length = strcspn(stra, strc); /* length = 9 */
```
strerror

**String Error**

**Syntax**

```c
#include <string.h>
char *strerror(int errno);
```

**Syntax for C++**

```cpp
#include <cstring>
char *std::strerror(int errno);
```

**Defined in**

strerror.c in rts.src

**Description**

The `strerror` function returns the string "string error". This function is supplied to provide ISO compatibility.

strftime

**Format Time**

**Syntax**

```c
#include <time.h>
size_t strftime(char *s, size_t maxsize, const char *format, const struct tm *timeptr);
```

**Syntax for C++**

```cpp
#include <ctime>
size_t std::strftime(char *s, size_t maxsize, const char *format, const struct tm *timeptr);
```

**Defined in**

strftime.c in rts.src

**Description**

The `strftime` function formats a time (pointed to by `timeptr`) according to a format string and returns the formatted time in the string `s`. Up to `maxsize` characters can be written to `s`. The format parameter is a string of characters that tells the `strftime` function how to format the time; the following list shows the valid characters and describes what each character expands to.

<table>
<thead>
<tr>
<th>Character</th>
<th>Expands to</th>
</tr>
</thead>
<tbody>
<tr>
<td>%a</td>
<td>The abbreviated weekday name (Mon, Tue, . . .)</td>
</tr>
<tr>
<td>%A</td>
<td>The full weekday name</td>
</tr>
<tr>
<td>%b</td>
<td>The abbreviated month name (Jan, Feb, . . .)</td>
</tr>
<tr>
<td>%B</td>
<td>The locale's full month name</td>
</tr>
<tr>
<td>%c</td>
<td>The date and time representation</td>
</tr>
<tr>
<td>%d</td>
<td>The day of the month as a decimal number (0–31)</td>
</tr>
<tr>
<td>%H</td>
<td>The hour (24-hour clock) as a decimal number (00–23)</td>
</tr>
</tbody>
</table>
### strlen

**Find String Length**

**Syntax**

```c
#include <string.h>

size_t strlen(const char *string);
```

**Syntax for C++**

```cpp
#include <cstring>

size_t std::strlen(const char *string);
```

**Defined in**

`strlen.c` in `rts.src`

**Description**

The `strlen` function returns the length of the string. In C, a character string is terminated by the first byte with a value of 0 (a null character). The returned result does not include the terminating null character.

**Example**

```c
char *stra = "who is there?";
char *strb = "abcdefghijklmnopqrstuvwxyz";
char *strc = "abcdefg";
size_t length;

length = strlen(stra); /* length = 13 */
length = strlen(strb); /* length = 26 */
length = strlen(strc); /* length = 7 */
```
**strncat**

_Concatenate Strings_

**Syntax**

```c
#include <string.h>
char *strncat(char *dest, const char *src, size_t n);
```

**Syntax for C++**

```cpp
#include <cstring>
char *std::strncat(char *dest, const char *src, size_t n);
```

**Defined in**

strncat.c in rts.src

**Description**

The `strncat` function appends up to `n` characters of `s2` (including a terminating null character) to `dest`. The initial character of `src` overwrites the null character that originally terminated `dest`; `strncat` appends a null character to the result. The function returns the value of `dest`.

**Example**

In the following example, the character strings pointed to by `*a`, `*b`, and `*c` were assigned the values shown in the comments. In the comments, the notation `\0` represents the null character:

```c
char *a, *b, *c;
size_t size = 13;
.. .. ..
/* a---> "I do not like them,\0" */;
/* b---> " Sam I am, \0" */;
/* c---> "I do not like green eggs and ham\0" */;
strncat (a,b,size);
/* a---> "I do not like them, Sam I am, \0" */;
/* b---> " Sam I am, \0" */;
/* c---> "I do not like green eggs and ham\0" */;
strncat (a,c,size);
/* a---> "I do not like them, Sam I am, I do not like\0" */;
/* b---> " Sam I am, \0" */;
/* c---> "I do not like green eggs and ham\0" */;
```
**strncmp**

**Compare Strings**

**Syntax**

```c
#include <string.h>

int strncmp(const char *string1, const char *string2, size_t n);
```

**Syntax for C++**

```c
#include <cstring>

int std::strncmp(const char *string1, const char *string2, size_t n);
```

**Defined in**

strncmp.c in rts.src

**Description**

The strncmp function compares up to n characters of s2 with s1. The function returns one of the following values:

- `< 0` if `*string1` is less than `*string2`
- `0` if `*string1` is equal to `*string2`
- `> 0` if `*string1` is greater than `*string2`

**Example**

```c
char *stra = "why ask why";
char *strb = "just do it";
char *strc = "why not?";
size_t size = 4;
if (strcmp(stra, strb, size) > 0) {
    /* statements here will get executed */
}
if (strcmp(stra, strc, size) == 0) {
    /* statements here will get executed also */
}
```

**strncpy**

**String Copy**

**Syntax**

```c
#include <string.h>

char *strncpy(char *dest, const char *src, size_t n);
```

**Syntax for C++**

```c
#include <cstring>

char *std::strncpy(char *dest, const char *src, size_t n);
```

**Defined in**

strncpy.c in rts.src

**Description**

The strncpy function copies up to n characters from src into dest. If src is n characters long or longer, the null character that terminates src is not copied. If you attempt to copy characters from overlapping strings, the function's behavior is undefined. If src is shorter than n characters, strncpy appends null characters to dest so that dest contains n characters. The function returns the value of dest.
Example

Note that strb contains a leading space to make it five characters long. Also note that the first five characters of strc are an I, a space, the word am, and another space, so that after the second execution of strncpy, stra begins with the phrase I am followed by two spaces. In the comments, the notation \0 represents the null character.

```c
char stra[] = "she's the one mother warned you of";
char strb[] = "he's";
char strc[] = "I am the one father warned you of";
char strd[] = "oops";
int length = 5;

strncpy (stra,strb,length);
/* stra−−> "he's the one mother warned you of\0" */;
/* strb−−> "he's\0" */;
/* strc−−> "I am the one father warned you of\0" */;
/* strd−−> "oops\0" */;

strncpy (stra,strc,length);
/* stra−−> "I am the one father warned you of\0" */;
/* strb−−> "he's\0" */;
/* strc−−> "I am the one father warned you of\0" */;
/* strd−−> "oops\0" */;

strncpy (stra,strd,length);
/* stra−−> "oops\0" */;
/* strb−−> "he's\0" */;
/* strc−−> "I am the one father warned you of\0" */;
/* strd−−> "oops\0" */;
```

Find Any Matching Character

Syntax

```c
#include <string.h>
char *strpbrk(const char *string, const char *chs);
```

Syntax for C++

```cpp
#include <cstring>
char *std::strpbrk(const char *string, const char *chs);
```

Defined in

strpbrk.c in rts.src

Description

The strpbrk function locates the first occurrence in string of any character in chs. If strpbrk finds a matching character, it returns a pointer to that character; otherwise, it returns a null pointer (0).

Example

```c
char *stra = "it wasn't me";
char *strb = "wave";
char *a;

a = strpbrk (stra,strb);
```

After this example, *a points to the w in wasn't.
**strchr**

*Find Last Occurrence of a Character*

**Syntax**

```c
#include <string.h>
char *strchr(const char *string, int c);
```

**Syntax for C++**

```c
#include <cstring>
char *std::strchr(const char *string, int c);
```

**Defined in**

strchr.c in rts.src

**Description**

The strchr function finds the last occurrence of c in string. If strchr finds the character, it returns a pointer to the character; otherwise, it returns a null pointer (0).

**Example**

```c
char *a = "When zz comes home, the search is on for zs";
char *b;
char the_z = 'z';
```

After this example, *b points to the z in zs near the end of the string.

---

**strspn**

*Find Number of Matching Characters*

**Syntax**

```c
#include <string.h>
size_t *strspn(const char *string, const char *chs);
```

**Syntax for C++**

```c
#include <cstring>
size_t *std::strspn(const char *string, const char *chs);
```

**Defined in**

strspn.c in rts.src

**Description**

The strspn function returns the length of the initial segment of string, which is entirely made up of characters in chs. If the first character of string is not in chs, the strspn function returns 0.

**Example**

```c
char *stra = "who is there?";
char *strb = "abcdefghijklmnopqrstuvwxyz";
char *strc = "abcdefg";
size_t length;
length = strspn(stra, strb); /* length = 3 */
length = strspn(stra, strc); /* length = 0 */
```
**strstr**

*Find Matching String*

**Syntax**
```c
#include <string.h>
char *strstr(const char *string1, const char *string2);
```

**Syntax for C++**
```c
#include <cstring>
char *std::strstr(const char *string1, const char *string2);
```

**Defined in**
strstr.c in rts.src

**Description**
The strstr function finds the first occurrence of string2 in string1 (excluding the terminating null character). If strstr finds the matching string, it returns a pointer to the located string; if it doesn’t find the string, it returns a null pointer. If string2 points to a string with length 0, strstr returns string1.

**Example**
```c
char *stra = "so what do you want for nothing?";
char *strb = "what";
char *ptr;
ptr = strstr(stra,strb);
```
The pointer *ptr now points to the w in what in the first string.

---

**strtod/strtol/strtoul/strtoll/strtoull**

*String to Number*

**Syntax**
```c
#include <stdlib.h>
double      strtod(const char *st, char **endptr);
long        strtol(const char *st, char **endptr, int base);
unsigned long strtoul(const char *st, char **endptr, int base);
long long   strtoll(const char *st, char **endptr, int base);
unsigned long long strtoull(const char *st, char **endptr, int base);
```

**Syntax for C++**
```c
#include <cstdlib>
double      std::strtod(const char *st, char **endptr);
long        std::strtol(const char *st, char **endptr, int base);
unsigned long std::strtoul(const char *st, char **endptr, int base);
long long   std::strtoll(const char *st, char **endptr, int base);
unsigned long long std::strtoull(const char *st, char **endptr, int base);
```

**Defined in**
strtod.c, strtol.c, and strtoul.c in rts.src

**Description**
Three functions convert ASCII strings to numeric values. For each function, argument st points to the original string. Argument endptr points to a pointer; the functions set this pointer to point to the first character after the converted string. The functions that convert to integers also have a third argument, base, which tells the function what base to interpret the string in.
The strtok function converts a string to a floating-point value. The string must have the following format:

```
[space] [sign] digits [.digits] [e|E [sign] integer]
```

The function returns the converted string; if the original string is empty or does not have the correct format, the function returns a 0. If the converted string would cause an overflow, the function returns ±HUGE_VAL; if the converted string would cause an underflow, the function returns 0. If the converted string overflows or an underflows, errno is set to the value of ERANGE.

The strtol function converts a string to a long integer. The string must have the following format:

```
[space] [sign] digits [.digits] [e|E [sign] integer]
```

The strtoul function converts a string to an unsigned long integer. The string must have the following format:

```
[space] [sign] digits [.digits] [e|E [sign] integer]
```

The space is indicated by a horizontal or vertical tab, space bar, carriage return, form feed, or new line. Following the space is an optional sign and digits that represent the integer portion of the number. The fractional part of the number follows, then the exponent, including an optional sign.

The first unrecognized character terminates the string. The pointer that endptr points to is set to point to this character.

---

**strtok**

*Break String into Token*

**Syntax**

```c
#include <string.h>

char *strtok(char *str1, const char *str2);
```

**Syntax for C++**

```c++
#include <cstdio>

char *std::strtok(char *str1, const char *str2);
```

**Defined in**

strtok.c in rts.src

**Description**

Successive calls to the strtok function break str1 into a series of tokens, each delimited by a character from str2. Each call returns a pointer to the next token.
strxfrm

Example
After the first invocation of strtok in the example below, the pointer stra points to the string excuse\0 because strtok has inserted a null character where the first space used to be. In the comments, the notation \0 represents the null character.

char stra[] = "excuse me while I kiss the sky";
char *ptr;
ptr = strtok (stra, " "); /* ptr -> "excuse\0" */
ptr = strtok (0, " "); /* ptr -> "me\0" */
ptr = strtok (0, " "); /* ptr -> "while\0" */

strxfrm
Convert Characters

Syntax
#include <string.h>
size_t strxfrm(char *to, const char *from, size_t n);

Syntax for C++
#include <cstring>
size_t std::strxfrm(char *to, const char *from, size_t n);

Description
The strxfrm function converts n characters pointed to by from into the n characters pointed to by to.

tan
Tangent

Syntax
#include <math.h>
double tan(double x);

Syntax for C++
#include <cmath>
double std::tan(double x);

Defined in
tan.c in rts.src

Description
The tan function returns the tangent of a floating-point number x. The angle x is expressed in radians. An argument with a large magnitude can produce a result with little or no significance.

Example
double x, y;
x = 3.1415927/4.0;
y = tan(x); /* return value = 1.0 */
### tanh

**Hyperbolic Tangent**

**Syntax**

```c
#include <math.h>

double tanh(double x);
```

**Syntax for C++**

```cpp
#include <cmath>

double std::tanh(double x);
```

**Defined in**

tanh.c in rts.src

**Description**

The tanh function returns the hyperbolic tangent of a floating-point number x.

**Example**

```c
double x, y;
x = 0.0;
y = tanh(x);        /* return value = 0.0 */
```

---

### time

**Time**

**Syntax**

```c
#include <time.h>

time_t time(time_t *timer);
```

**Syntax for C++**

```cpp
#include <ctime>

time_t std::time(time_t *timer);
```

**Defined in**

time.c in rts.src

**Description**

The time function determines the current calendar time, represented in seconds. If the calendar time is not available, the function returns −1. If timer is not a null pointer, the function also assigns the return value to the object that timer points to.

For more information about the functions and types that the time.h header declares and defines, see section 7.3.17, *Time Functions (time.h)*, on page 7-27.

---

**Note: The time Function Is Target-System Specific**

The time function is target-system specific, so you must write your own time function.
**tmpfile**

Create Temporary File

Syntax

```c
#include <stdio.h>
FILE *tmpfile(void);
```

Syntax for C++

```cpp
#include <cstdio>
FILE *std::tmpfile(void);
```

Defined in
tmpfile.c in rts.src

Description

The tmpfile function creates a temporary file.

**tmpnam**

Generate Valid Filename

Syntax

```c
#include <stdio.h>
char *tmpnam(char *s);
```

Syntax for C++

```cpp
#include <cstdio>
char *std::tmpnam(char *s);
```

Defined in
tmpnam.c in rts.src

Description

The tmpnam function generates a string that is a valid filename.

**toascii**

Convert to ASCII

Syntax

```c
#include <ctype.h>
int toascii(int c);
```

Syntax for C++

```cpp
#include <cctype>
int toascii(int c);
```

Defined in
toascii.c in rts.src

Description

The toascii function ensures that `c` is a valid ASCII character by masking the lower seven bits. There is also an equivalent macro call `_toascii`. 7-96
**tolower/toupper**  
*Convert Case*

**Syntax**

```c
#include <ctype.h>

int tolower(int c);
int toupper(int c);
```

**Syntax for C++**

```c
#include <cctype>

int std::tolower(int c);
int std::toupper(int c);
```

**Defined in**
tolower.c and toupper.c in rts.src

**Description**

Two functions convert the case of a single alphabetic character c into upper case or lower case:

- The tolower function converts an uppercase argument to lowercase. If c is already in lowercase, tolower returns it unchanged.

- The toupper function converts a lowercase argument to uppercase. If c is already in uppercase, toupper returns it unchanged.

The functions have macro equivalents named _tolower and _toupper.

---

**ungetc**  
*Write Character to Stream*

**Syntax**

```c
#include <stdio.h>

int ungetc(int c, FILE *fp);
```

**Syntax for C++**

```c
#include <cstdio>

int std::ungetc(int c, FILE *fp);
```

**Defined in**
ungetc.c in rts.src

**Description**

The ungetc function writes the character c to the stream pointed to by _fp.
Variable-Argument Macros

Syntax

```c
#include <stdarg.h>
typedef char *va_list;
type va_arg(va_list, _type);
void va_end(va_list);
void va_start(va_list, parmN);
```

Syntax for C++

```cpp
#include <cstdarg>
typedef char *std::va_list;
type std::va_arg(va_list, _type);
void std::va_end(va_list);
void std::va_start(va_list, parmN);
```

Defined in

stdarg.h/cstdarg

Description

Some functions are called with a varying number of arguments that have varying types. Such a function, called a variable-argument function, can use the following macros to step through its argument list at run time. The _ap parameter points to an argument in the variable-argument list.

- The va_start macro initializes _ap to point to the first argument in an argument list for the variable-argument function. The parmN parameter points to the right-most parameter in the fixed, declared list.
- The va_arg macro returns the value of the next argument in a call to a variable-argument function. Each time you call va_arg, it modifies _ap so that successive arguments for the variable-argument function can be returned by successive calls to va_arg (va_arg modifies _ap to point to the next argument in the list). The type parameter is a type name; it is the type of the current argument in the list.
- The va_end macro resets the stack environment after va_start and va_arg are used.

Note that you must call va_start to initialize _ap before calling va_arg or va_end.
Example

```c
int printf (char *fmt...) 
  va_list ap; 
  va_start(ap, fmt); 
  .
  .
  i = va_arg(ap, int); /* Get next arg, an integer */ 
  .
  s = va_arg(ap, char *); /* Get next arg, a string */ 
  .
  l = va_arg(ap, long); /* Get next arg, a long */ 
  .
  .
  va_end(ap); /* Reset */ 
} 
```

vfprintf

**Write to Stream**

**Syntax**

```c
#include <stdio.h>
int vfprintf(FILE *_fp, const char *_format, char *_ap);
```

**Syntax for C++**

```c
#include <cstdio>
int std::vfprintf(FILE *_fp, const char *_format, char *_ap);
```

**Defined in**

vfprintf.c in rts.src

**Description**

The vfprintf function writes to the stream pointed to by _fp. The string pointed to by format describes how to write the stream. The argument list is given by _ap.

vprintf

**Write to Standard Output**

**Syntax**

```c
#include <stdio.h>
int vprintf(const char *format, char *_ap);
```

**Syntax for C++**

```c
#include <cstdio>
int std::vprintf(const char *format, char *ap);
```

**Defined in**

vprintf.c in rts.src

**Description**

The vprintf function writes to the standard output device. The string pointed to by _format describes how to write the stream. The argument list is given by _ap.
vsnprintf

Syntax
#include <stdio.h>

int vsnprintf(char * _string, size_t n, const char * _format, char * _ap);

Syntax for C++
#include <cstdio>

int std::vsnprintf(char * _string, size_t n, const char * _format, char * _ap);

Defined in
vsnprintf.c in rts.src

Description
The vsnprintf function writes up to n characters to the array pointed to by
_string. The string pointed to by _format describes how to write the stream.
The argument list is given by _ap. Returns the number of characters that
would have been written if no limit had been placed on the string.

vsprintf

Syntax
#include <stdio.h>

int vsprintf(char *string, const char * _format, char * _ap);

Syntax for C++
#include <cstdio>

int std::vsprintf(char * _string, const char * _format, char * _ap);

Defined in
vsprintf.c in rts.src

Description
The vsprintf function writes to the array pointed to by _string. The string pointed
to by _format describes how to write the stream. The argument list is given
by _ap.
When using the TMS320C55x™ C/C++ compiler, you can compile your code under a number of different configurations and options that are not necessarily compatible with one another. Since it would be cumbersome to include all possible combinations in individual run-time-support libraries, this package includes the source archive, rts.src, which contains all run-time-support functions.

You can build your own run-time-support libraries by using the mk55 utility described in this chapter and the archiver described in the TMS320C55x Assembly Language Tools User’s Guide.

</tbody>
</table>
8.1 Invoking the Library-Build Utility

The syntax for invoking the library-build utility is:

```
mk55 [options] src_arch1 [-l obj.lib1] [src_arch2 [-l obj.lib2]] ...
```

`mk55` Command that invokes the utility.

`options` Options affect how the library-build utility treats your files. Options can appear anywhere on the command line or in a linker command file. (Options are discussed in sections 8.2 and 8.3.)

`src_arch` The name of a source archive file. For each source archive named, mk55 builds an object library according to the run-time model specified by the command-line options.

`-l obj.lib` The optional object library name. If you do not specify a name for the library, mk55 uses the name of the source archive and appends a `.lib` suffix. For each source archive file specified, a corresponding object library file is created. You cannot build an object library from multiple source archive files.

The mk55 utility runs the compiler on each source file in the archive to compile and/or assemble it. Then, the utility collects all the object files into the object library. All the tools must be in your PATH environment variable. The utility ignores the environment variables `C55X_C_OPTION`, `C_OPTION`, `C55X_C_DIR`, and `C_DIR`. 
8.2 Library-Build Utility Options

Most of the options that are included on the command line correspond directly to options of the same name used with the compiler, assembler, linker, and shell. The following options apply only to the library-build utility.

--c  Extracts C source files contained in the source archive from the library and leaves them in the current directory after the utility completes execution.

--h  Uses header files contained in the source archive and leaves them in the current directory after the utility completes execution. Use this option to install the run-time-support header files from the rts.src archive that is shipped with the tools.

--k  Overwrite files. By default, the utility aborts any time it attempts to create an object file when an object file of the same name already exists in the current directory, regardless of whether you specified the name or the utility derived it.

--q  Suppress header information (quiet).

--u  Does not use the header files contained in the source archive when building the object library. If the desired headers are already in the current directory, there is no reason to reinstall them. This option gives you flexibility in modifying run-time-support functions to suit your application.

--v  Prints progress information to the screen during execution of the utility. Normally, the utility operates silently (no screen messages).
8.3 Options Summary

The other options you can use with the library-build utility correspond directly to the options used with the compiler and assembler. Table 8–1 lists these options. These options are described in detail on the indicated page below.

Table 8–1. Summary of Options and Their Effects

(a) Options that control the compiler/shell

<table>
<thead>
<tr>
<th>Option</th>

</tr>
</tbody>
</table>
The C++ compiler implements function overloading, operator overloading, and type-safe linking by encoding a function’s signature in its link-level name. The process of encoding the signature into the linkname is often referred to as name mangling. When you inspect mangled names, such as in assembly files or linker output, it can be difficult to associate a mangled name with its corresponding name in the C++ source code. The C++ name demangler is a debugging aid that translates each mangled name it detects to its original name found in the C++ source code.

These topics tell you how to invoke and use the C++ name demangler. The C++ name demangler reads in input, looking for mangled names. All unmangled text is copied to output unaltered. All mangled names are demangled before being copied to output.

<tr>
<td>9.3 Sample Usage of the C++ Name Demangler</td>
<td>9-3</td>
</tr>
</tbody>
</table>
9.1 Invoking the C++ Name Demangler

The syntax for invoking the C++ name demangler is:

```
 dem55 [options][filenames]
```

- **dem55**: Command that invokes the C++ name demangler.
- **options**: Options affect how the name demangler behaves. Options can appear anywhere on the command line or in a linker command file. (Options are discussed in section 9.2.)
- **filenames**: Text input files, such as the assembly file output by the compiler, the assembler listing file, and the linker map file. If no filenames are specified on the command line, dem55 uses standard in.

By default, the C++ name demangler sends output to standard out. You can use the `−o file` option if you want to send output to a file.

9.2 C++ Name Demangler Options

Following are the options that control the C++ name demangler, along with descriptions of their effects.

- **−h**: Prints a help screen that provides an online summary of the C++ name demangler options
- **−o file**: Sends output to the given file rather than to standard out
- **−u**: Specifies that external names do not have a C++ prefix
- **−v**: Enables verbose mode (outputs a banner)
9.3 Sample Usage of the C++ Name Demangler

Example 9−1 shows a sample C++ program and the resulting assembly code output of the TMS320C55x™ compiler. In Example 9−1(a), the linknames of all the functions are mangled; that is, their signature information is encoded into their names.

Example 9−1. Name Mangling

(a) C++ Program

```cpp
class banana {
    public:
        int calories(void);
        banana();
        ~banana();
    };

    int calories_in_a_banana(void) {
        banana x;
        return x.calories();
    }
```

(b) Assembly output for calories_in_a_banana

```
_calories_in_a_banana__Fv:
 AADD #−3, SP
 MOV SP, AR0
 AMAR *AR0+
 CALL #__ct__6bananaFv
 MOV SP, AR0
 AMAR *AR0+
 CALL #_calories__6bananaFv
 MOV SP, AR0
 MOV T0, *SP(#0)
 MOV #2, T0
 AMAR *AR0+
 CALL #_dt__6bananaFv
 MOV *SP(#0), T0
 AADD #3, SP
 RET
```
Sample Usage of the C++ Name Demangler

Executing the C++ name demangler demangles all names that it believes to be mangled. If you enter:

```bash
% dem55 banana.asm
```

the result is shown in Example 9–2. Notice that the linknames of the functions are demangled.

**Example 9–2. Result After Running the C++ Name Demangler**

```
_calories_in_a_banana():
  AADD #−3, SP
  MOV SP, AR0
  AMAR *AR0+
  CALL #banana::banana()
  MOV SP, AR0
  AMAR *AR0+
  CALL #banana::_calories()
  MOV SP, AR0
  MOV T0, *SP(#0)
  MOV #2, T0
  AMAR *AR0+
  CALL #banana::~banana()
  MOV *SP(#0), T0
  AADD #3, SP
  RET
```

alias disambiguation: A technique that determines when two pointer expressions cannot point to the same location, allowing the compiler to freely optimize such expressions.

aliasing: Aliasing occurs when a single object can be accessed in more than one way, such as when two pointers point to a single object. It can disrupt optimization, because any indirect reference could refer to any other object.

allocation: A process in which the linker calculates the final memory addresses of output sections.

archive library: A collection of individual files grouped into a single file by the archiver.

archiver: A software program that collects several individual files into a single file called an archive library. The archiver allows you to add, delete, extract, or replace members of the archive library.

assembler: A software program that creates a machine-language program from a source file that contains assembly language instructions, directives, and macro definitions. The assembler substitutes absolute operation codes for symbolic operation codes and absolute or relocatable addresses for symbolic addresses.

assignment statement: A statement that initializes a variable with a value.

autoinitialization: The process of initializing global C variables (contained in the .cinit section) before program execution begins.

autoinitialization at load time: An autoinitialization method used by the linker when linking C code. The linker uses this method when you invoke the linker with the –cr option. This method initializes variables at load time instead of run time.
autoinitialization at run time: An autoinitialization method used by the linker when linking C code. The linker uses this method when you invoke the linker with the −c option. The linker loads the .cinit section of data tables into memory, and variables are initialized at run time.

big-endian: An addressing protocol in which bytes are numbered from left to right within a word. More significant bytes in a word have lower numbered addresses. Endian ordering is hardware-specific and is determined at reset. See also little endian.

block: A set of statements that are grouped together with braces and treated as an entity.

.bss section: One of the default COFF sections. You can use the .bss directive to reserve a specified amount of space in the memory map that you can use later for storing data. The .bss section is uninitialized.

byte: The smallest addressable unit of storage that can contain a character.

C compiler: A software program that translates C source statements into assembly language source statements.

code generator: A compiler tool that takes the file produced by the parser or the optimizer and produces an assembly language source file.

command file: A file that contains linker or hex conversion utility options and names input files for the linker or hex conversion utility.

comment: A source statement (or portion of a source statement) that documents or improves readability of a source file. Comments are not compiled, assembled, or linked; they have no effect on the object file.

common object file format (COFF): A binary object file format that promotes modular programming by supporting the concept of sections. All COFF sections are independently relocatable in memory space; you can place any section into any allocated block of target memory.

constant: A type whose value cannot change.

cross-reference listing: An output file created by the assembler that lists the symbols it defined, what line they were defined on, which lines referenced them, and their final values.
**.data section:** One of the default COFF sections. The .data section is an initialized section that contains initialized data. You can use the .data directive to assemble code into the .data section.

**direct call:** A function call where one function calls another using the function’s name.

**directives:** Special-purpose commands that control the actions and functions of a software tool.

**disambiguation:** See *alias disambiguation*

**dynamic memory allocation:** A technique used by several functions (such as malloc, calloc, and realloc) to dynamically allocate memory for variables at run time. This is accomplished by defining a large memory pool (heap) and using the functions to allocate memory from the heap.

**emulator:** A development system used to test software directly on TMS320C55x™ hardware.

**entry point:** A point in target memory where execution starts.

**environment variable:** System symbol that you define and assign to a string. They are often included in batch files, for example, .cshrc.

**epilog:** The portion of code in a function that restores the stack and returns.

**executable module:** A linked object file that can be executed in a target system.

**expression:** A constant, a symbol, or a series of constants and symbols separated by arithmetic operators.

**external symbol:** A symbol that is used in the current program module but defined or declared in a different program module.
file-level optimization: A level of optimization where the compiler uses the information that it has about the entire file to optimize your code (as opposed to program-level optimization, where the compiler uses information that it has about the entire program to optimize your code).

function inlining: The process of inserting code for a function at the point of call. This saves the overhead of a function call, and allows the optimizer to optimize the function in the context of the surrounding code.

global symbol: A symbol that is either defined in the current module and accessed in another or accessed in the current module but defined in another.

indirect call: A function call where one function calls another function by giving the address of the called function.

initialized section: A COFF section that contains executable code or data. An initialized section can be built with the .data, .text, or .sect directive.

integrated preprocessor: A C preprocessor that is merged with the parser, allowing for faster compilation. Standalone preprocessing or preprocessed listing is also available.

interlist: A feature that inserts as comments your original C source statements into the assembly language output from the assembler. The C statements are inserted next to the equivalent assembly instructions.

ISO: International Organization for Standardization. A worldwide federation of national standards bodies, which establishes international standards voluntarily followed by industries.

kernel: The body of a software-pipelined loop between the pipelined-loop prolog and the pipelined-loop epilog.

K&R C: Kernighan and Ritchie C, the de facto standard as defined in the first edition of The C Programming Language (K&R). Most K&R C programs written for earlier, non-ISO C compilers correctly compile and run without modification.
label: A symbol that begins in column 1 of an assembler source statement and corresponds to the address of that statement. A label is the only assembler statement that can begin in column 1.

linker: A software program that combines object files to form an object module that can be allocated into system memory and executed by the device.

listing file: An output file created by the assembler that lists source statements, their line numbers, and their effects on the section program counter (SPC).

little endian: An addressing protocol in which bytes are numbered from right to left within a word. More significant bytes in a word have higher numbered addresses. Endian ordering is hardware-specific and is determined at reset. See also big endian

loader: A device that loads an executable module into system memory.

loop unrolling: An optimization that expands small loops so that each iteration of the loop appears in your code. Although loop unrolling increases code size, it can improve the efficiency of your code.

macro: A user-defined routine that can be used as an instruction.

macro call: The process of invoking a macro.

macro definition: A block of source statements that define the name and the code that make up a macro.

macro expansion: The process of inserting source statements into your code in place of a macro call.

map file: An output file, created by the linker, that shows the memory configuration, section composition, section allocation, symbol definitions, and the addresses at which the symbols were defined for your program.

memory map: A map of target system memory space that is partitioned into functional blocks.
object file: An assembled or linked file that contains machine-language object code.

object library: An archive library made up of individual object files.

operand: An argument of an assembly language instruction, assembler directive, or macro directive that supplies information to the operation performed by the instruction or directive.

optimizer: A software tool that improves the execution speed and reduces the size of C programs.

options: Command parameters that allow you to request additional or specific functions when you invoke a software tool.

output module: A linked, executable object file that can be downloaded and executed on a target system.

output section: A final, allocated section in a linked, executable module.

parser: A software tool that reads the source file, performs preprocessing functions, checks the syntax, and produces an intermediate file that can be used as input for the optimizer or code generator.

pragma: Preprocessor directive that provides directions to the compiler about how to treat a particular statement.

preprocessor: A software tool that interprets macro definitions, expands macros, interprets header files, interprets conditional compilation, and acts upon preprocessor directives.

program-level optimization: An aggressive level of optimization where all of the source files are compiled into one intermediate file. Because the compiler can see the entire program, several optimizations are performed with program-level optimization that are rarely applied during file-level optimization.
relocation: A process in which the linker adjusts all the references to a symbol when the symbol’s address changes.

run-time environment: The run-time parameters in which your program must function. These parameters are defined by the memory and register conventions, stack organization, function call conventions, and system initialization.

run-time-support functions: Standard ISO functions that perform tasks that are not part of the C language (such as memory allocation, string conversion, and string searches).

run-time-support library: A library file, rts.src, that contains the source for the run-time-support functions.

section: A relocatable block of code or data that ultimately occupies contiguous space in the memory map.

section header: A portion of a COFF object file that contains information about a section in the file. Each section has its own header. The header points to the section’s starting address, contains the section’s size, etc.

shell program: A utility that lets you compile, assemble, and optionally link in one step. The shell runs one or more source modules through the compiler (including the parser, optimizer, and code generator), the assembler, and the linker.

simulator: A development system used to test software on a workstation without C55x hardware.

source file: A file that contains C code or assembly language code that is compiled or assembled to form an object file.

standalone preprocessor: A software tool that expands macros, #include files, and conditional compilation as an independent program. It also performs integrated preprocessing, which includes parsing of instructions.

static variable: A kind of variable whose scope is confined to a function or a program. The values of static variables are not discarded when the function or program is exited; their previous value is resumed when the function or program is reentered.
**storage class:** Any entry in the symbol table that indicates how to access a symbol.

**structure:** A collection of one or more variables grouped together under a single name.

**symbol:** A string of alphanumeric characters that represents an address or a value.

**symbol table:** A portion of a COFF object file that contains information about the symbols that are defined and used by the file.

**symbolic debugging:** The ability of a software tool to retain symbolic information that can be used by a debugging tool such as a simulator or an emulator.

**target system:** The system on which the object code you have developed is executed.

**.text section:** One of the default COFF sections. The .text section is initialized and contains executable code. You can use the .text directive to assemble code into the .text section.

**trigraph sequence:** A three character sequence that has a meaning (as defined by the ISO 646-1983 Invariant Code Set). These characters cannot be represented in the C character set and are expanded to one character. For example, the trigraph `??` is expanded to `^`.

**uninitialized section:** A COFF section that reserves space in the memory map but that has no actual contents. These sections are built up with the .bss and .usect directives.

**unsigned value:** A value that is treated as a nonnegative number, regardless of its actual sign.

**variable:** A symbol representing a quantity that may assume any of a set of values.

described 3-17
aliasing 3-10
definition A-1
allocation A-1
alternate directories for include files 2-35
ANSI A-1
ANSI C, language 5-1, 5-38, 7-84, 7-86
−apd assembler option 2-27
−api assembler option 2-27
−ar assembler option 2-27
−ar linker option 4-5
assembler 1-3
−ats assembler option 2-28
definition A-1
enable pipeline conflict warnings (−aw option) 2-29
options 2-27
suppressing warning messages 2-29
assembly code speed, −ath assembler option 2-28
assembly language
interfacing with C language 6-22 to 6-37
interlisting with C language modules 6-22 to 6-24
assembly listing file, creating 2-27
assembly source debugging 2-23
assert function 7-41
assert.h header 7-17
summary of functions 7-30
assignment statement A-1
−ata assembler option 2-28
atan function 7-42
arc cosine 7-40
arc sine 7-41
arc tangent 7-42
archive library 4-8, A-1
archiver 1-3, A-1
−−args linker option 4-5
argument block, described 6-16
ARMS mode, −ata assembler option 2-28
−as assembler option 2-28
ASCII conversion functions 7-43
asctime function 7-40, 7-48
asin function 7-41
.asm extension 2-24
changing 2-25
asm statement 6-27
C language 5-16
in optimized code 3-9
assembler 1-3
−ats assembler option 2-28
definition A-1
enable pipeline conflict warnings (−aw option) 2-29
options 2-27
suppressing warning messages 2-29
assembly code speed, −ath assembler option 2-28
assembly language
interfacing with C language 6-22 to 6-37
interlisting with C language modules 6-22 to 6-24
assembly listing file, creating 2-27
assembly source debugging 2-23
assert function 7-41
assert.h header 7-17
summary of functions 7-30
assignment statement A-1
−ata assembler option 2-28
atan function 7-42
arc cosine 7-40
arc sine 7-41
arc tangent 7-42
archive library 4-8, A-1
archiver 1-3, A-1
−−args linker option 4-5
argument block, described 6-16
ARMS mode, −ata assembler option 2-28
−as assembler option 2-28
ASCII conversion functions 7-43
asctime function 7-40, 7-48
asin function 7-41
.asm extension 2-24
changing 2-25
asm statement 6-27
C language 5-16
in optimized code 3-9
assembler 1-3
Index

atan2 function 7-42
−atb assembler option 2-28
−atc assembler option 2-28
atexit function 7-43 7-50
−ath assembler option 2-28
−atl assembler option 2-28
−atn assembler option 2-28
atof function 7-43

−ats assembler option 2-28
−at assembler option 2-28
−au assembler option 2-28
autoincrement addressing 3-22
autoinitialization 6-45 6-46, A-1
  at load time, definition A-1
  at run time, described 6-49
  of variables 6-7
  types of 4-10
auxiliary user information file, generating 2-17
−aw assembler option 2-29
−ax assembler option 2-29

B
−b option
  compiler 2-17
  linker 4-5
base-10 logarithm 7-66
big-endian, definition A-2
bit
  addressing 6-9
  fields 5-3, 6-9
bit fields 5-37
block
  allocating sections
    definition A-2
boot.asm 6-45
boot.obj 4-8, 4-10
branch optimizations 3-17
broken-down time 7-27 7-48 7-69
bsearch function 7-44
\.bss section
  definition
    A-2
buffer
  define and associate function 7-79
  specification function 7-77
byte A-2

C
.C extension 2-24
.c extension 2-24
C I/O
  implementation 7-6
  library 7-4 to 7-9
  low-level routines 7-6
C language
  accessing assembler constants 6-26
  accessing assembler variables 6-25
The C Programming Language 5-2
  characteristics
  compatibility with ISO C 5-35
  data types 5-6
  interfacing with assembly language 6-22 b
  interrupting with assembly
    preserving registers 6-38
    interrupt keyword 5-12
    interrupt routines 6-39
    ioport keyword 5-9
  keywords 5-8 to 5-14
  onchip keyword 5-12
  placing assembler statements in
    register variables 5-15
